By May 15, 1944 we had completed 1,181 treatment courses with the schedule of therapy we had adopted in July 1942. On this schedule the incidence of serious

3. Jones, N.; Carpenter, C. M.; Boak, R. A.; Warren, S. L., and Hanson, H.: The One Day Treatment of Syphilis with Fever and Mapharsen, Ven. Dis. Inform. 25: 99, 1944.

reactions is very low. As shown in table 3, the incidence of encephalopathy among our patients dropped from 1.43 per cent to 0.34 and the mortality rate is 1 in 1,181 instead of 1 in 300. Since our latest and, we hope, our last fatality we have slightly modified the schedule of treatment so that the mapharsen is injected in the late afternoon instead of the morning. This means that on the fever days the injection of mapharsen follows the fever instead of preceding it.

RESULTS OF TREATMENT

In compiling statistical results of treatment we have chosen six months as the minimum follow-up period which is likely to give a fairly accurate estimate of the effectiveness of the treatment. This period has been chosen both because the serologic tests of most patients with early syphilis become negative within six months after effective rapid therapy and because the majority of relapses occur within this period. A careful analysis of all the relapses or reinfections which have come to our attention at Bellevue Hospital following rapid

treatment for early syphilis makes us hesitate to distinguish between relapses and reinfections in compiling statistical tables. We believe that reinfections are much more frequent than relapses after six months. Consequently an observation period of six months enables us to differentiate somewhat between a fairly valuable follow-up and one that is less revealing of the probable results of treatment.

We excluded from the analysis of therapeutic results all patients lost within the first six months of follow-up, regardless of whether or not they had negative serologic tests when last seen. Patients with Wassermann titers less than 8, as reported by the New York State Department of Health serologic laboratory, are included among those with a satisfactory status because experience has proved that almost all such patients go on to become seronegative. Patients with Wassermann titers greater than 8 six months or more after treatment are reported as unsatisfactory results, although some of them may become seronegative without further treatment. This method of reporting is based on over four years of experience in observing quantitative serologic tests for syphilis. From our experience, as long as Wassermann titers of the blood are falling or remain at low levels, further treatment is not indicated.

As our case load at Bellevue Hospital has increased decidedly since August 1943, many patients treated according to the schedule of therapy we have just described have been followed for too short a period to be included in the present tabulation of results. It should also be stated that most of the patients on whom treatment results are reported did not receive bismuth in addition to mapharsen and fever. The percentage of patients kept under observation is not as high in this group as in previous groups, partly because of the increased case load but chiefly because of the increased number of sailors and transients admitted to the hospital for the rapid treatment of early syphilis.

Included among the treatment results summarized in table 4 is a relatively small group of patients who received a total of 0.54 Gm. of mapharsen and four fevers induced by typhoid vaccine prior to July 1942. This group is included because the treatment was similar and because the patients in it have been followed for longer periods.

The percentage of satisfactory results reported in table 4 is not quite as high as for most of the schedules of treatment published in our previous reports,⁴ but the differences are not very significant and the percentage of 80.7 satisfactory results is almost identical with that given in a recent report by Schoch and Alexander,⁵ who used much larger doses of mapharsen without the addition of fever.

138 East 36th Street.

ABSTRACT OF DISCUSSION

ON PAPERS OF DR. EAGLE, DRs. CANNON, FISHER,
RODRIGUEZ, BEATTIE AND MAECHLING AND
DRs. THOMAS AND WEXLER

DR. HERBERT RATTNER, Chicago: It is eleven years since Dr. Chargin and his associates introduced the five day treatment with neoarsphenamine. Since then many modifications of the original method have been introduced: the one day arsenofever method, which received so much premature publicity but of which little is heard today; the use of arsenic and bismuth administered concurrently in a course of five days; the syringe method, in which the drug is administered in seven, ten or twenty days, and the three methods reported today. Dr. Cannon concluded that his method had little merit. The methods of Eagle and Thomas are equally effective with respect to their "curative" values. With both methods there was an incidence of about 1:1,200 of fatal reactions. Thomas's fatality occurred in a pregnant woman, and he suggests therefore that pregnancy adds to the risk of intensive arsenotherapy. At our hospital we treated 29 pregnant women in all stages of pregnancy by the five day method without a serious reaction, and in each case there was a normal baby. With the method of Thomas the patient is isolated, rendered noninfectious quickly, wilful lapse from treatment is reduced to a minimum, and untoward reactions can be treated early. With Eagle's routine the patient continues at work, but inevitably when one relies on a patient to return of his own will there results a high lapse rate. Apparently any rapid method will cure the majority of patients who receive a sufficient amount of drug. Statistics indicate that the shorter the course of treatment, the greater the element of risk, but there are times when one must assume the risk. At the Cook County Hospital we used the five day method on 480 patients without a fatality. We attribute these good results in part to our willingness to discontinue treatment temporarily for the smallest reason—persistent headache, nausea or fever, and in such cases concentrated glucose was administered liberally.

4. Thomas, E. W., and Wexler, G.: Rapid Treatment of Early Syphilis with Multiple Injections of Mapharsen, *Am. J. Pub. Health* 31: 545, 1941; Rapid Treatment of Early Syphilis, *Arch. Dermat. & Syph.* 47: 553 (April) 1943.
5. Schoch, A. G., and Alexander, L. J.: Infections and Serologic Relapse During Intensive Arsenotherapy of Early Syphilis, *Am. J. Syph., Gonorr. & Ven. Dis.* 28: 221, 1944.

There are available to the physician a number of methods from which to choose that which is best suited to the patient's needs. Dr. Thomas's method is excellent for public practice. For the private patient who can be trusted to return for treatment, the Eagle method may be safer. For the traveling man who has but a week to give to treatment the five day treatment is eminently suitable. And if he wishes that there be no hospital record, one could use the Schoch syringe technic.

DR. E. A. STRAKOSCH, Chicago: From Oct. 31, 1942 through April 30, 1944 we started 515 patients on the Eagle-Hogan regimen at the Chicago Intensive Treatment Center. These were patients with primary, secondary or early latent syphilis who, on account of heart, chest or other pathologic findings, were ruled out from intensive fever-chemotherapy or the modification of the Schoch-Alexander treatment; 470 patients were started on the eight weeks and only 45 on the ten weeks schedule. It is noteworthy that only 211 patients completed their treatment. Of the 211, only 58 completed it on time; 132 patients became delinquent; 57 patients moved out of our jurisdiction—Army, Navy or somewhere else—and 103 patients stayed under our treatment. The range of delinquency goes up to 204 days. The treatment had to be discontinued in 12 patients because of nephrosis in 1 case, hepatitis after the fifth arsenic injection in another and severe bismuth stomatitis in 9 cases, and because of an uncooperative attitude in another. Seven patients were retreated: 1 with primary syphilis on account of serologic progression, 4 patients with secondary syphilis, 2 on account of cutaneous relapses, 2 on account of serologic relapse and 2 patients with latent syphilis whose Kahn titer was still positive or unchanged six months after the treatment was finished. These 7 patients took their treatment irregularly and did not finish it in time. It is my opinion that the Eagle-Hogan treatment method is a more practical, safer and to some extent better method than the other methods used by us, such as the fever-chemotherapy or the Schoch-Alexander method or its modifications. The definite disadvantage is the high treatment delinquency even in a treatment schedule as short as eight weeks.

DR. ARTHUR CURTIS, Ann Arbor, Mich.: By far the most serious complication of massive arsenotherapy is hemorrhagic encephalitis. Last fall Dr. Mallory and I, hoping to find some procedure which might enable us to anticipate the development of hemorrhagic encephalitis, set up the following experiment for patients receiving intensive arsenotherapy: On the day before treatment was begun, the first day of treatment, the third day of treatment and the fifth day of treatment, as well as two days after treatment ceased, the following procedures were done: a complete blood count, bleeding time, clotting time, prothrombin time, vitamin C level, positive pressure tourniquet test (Rumpel-Leede) and a negative pressure test. With these procedures we followed 58 consecutive patients on massive arsenotherapy. During this period there were 7 cases of hemorrhagic encephalitis with 2 fatalities. All patients that developed hemorrhagic encephalitis, with the exception of 1 male, had a positive pressure tourniquet test (Rumpel-Leede) before the onset of clinical symptoms. Since that time we have used the positive pressure tourniquet test (Rumpel-Leede) on all of our patients receiving intensive arsenotherapy. Treatment is stopped immediately on the appearance of any petechial hemorrhage by this test. We have not had a case of hemorrhagic encephalitis since that time.

DR. GEORGE N. SCHWEMLEIN, Chicago: The Section on Fever-Chemotherapy at the Chicago Intensive Treatment Center is continuing the study of the use of artificial fever combined with chemotherapy in early syphilis. Past experiences have demonstrated that this type of therapy has been beneficial in neurosyphilis and congenital and ocular syphilis; it was a natural step to investigate the effect of this procedure on the early stages of syphilis. We have employed a single eight hour session of artificial fever at 105 to 106 F. rectal level, with varying amounts of mapharsen and bismuth. On the basis of 1,500 patients treated the following observations may be noted: Combined artificial fever-chemotherapy is effective in completely arresting the disease; the method is advantageous in that relatively small amounts of mapharsen and bismuth are employed; the use of physically induced fever is as satisfactory as other methods; from the public health standpoint infectious syphilis can be quickly controlled in the vast majority of cases.

DR. J. R. DRIVER, Cleveland: It has been shown here today that a large proportion of patients treated for early infectious syphilis by short, intensive methods can be rendered noninfectious and probably cured. However, these methods are still experimental, are attended by more risks than the standard treatment procedures and should be used only by experts. Justification for their use lies chiefly in the control of large groups of early syphilitic infections that present a public health hazard especially in our large urban centers. The great majority of syphilitic infections occur among the most ignorant and least cooperative of our population. The difficulty in the past has been to keep them under treatment long enough to render them noninfectious. Therefore the desirability of intensive treatment procedures is obvious. With the Eagle method the patients are treated in the outpatient clinics, and the lapse rate due to uncooperative behavior is higher. In our treatment centers at the university hospitals and at the Cleveland City Hospital, out of 178 cases in which treatment was begun, completion of treatment was obtained in only 92. A few of these were given other forms of treatment because of vacations, but the great majority were lost as a result of uncooperative behavior. The advantage of the Thomas method lies in the fact that the patients are hospitalized during the entire course of treatment. Out of 252 cases in which we have begun treatment by this method, the course has been completed in 243. In 9 cases other forms of therapy were instituted because of severe reactions. In only 1 instance was treatment discontinued because of uncooperative behavior.

DR. ROY L. KILE, Cleveland: Dr. Driver has explained the series of cases we have observed in Cleveland on the Thomas-Wexler routine. There was one death, which Dr. George Binkley observed, wherein a batch of mapharsen was used that was outdated. This was the only serious reaction in 266 cases treated by this routine. I want to call attention to the fact that there may be some variation in different batches of mapharsen, more reactions having been noted with certain ones. The results with the Thomas-Wexler routine have been very satisfactory. The patients are hospitalized during their treatment and are free to return to work in a comparatively short time.

DR. ARTHUR G. SCHOCH, Dallas, Texas: The addition of bismuth to any arsenical regimen for the treatment of early syphilis seems to be a necessity. We thought that the addition of a rapidly acting oil soluble bismuth, bismuth ethyl camphorate, should be one step beyond the use of the slowly acting insoluble bismuth salicylate in oil. So far our results have been very encouraging. Using the Eagle triweekly schedule and substituting bismuth ethyl camphorate for bismuth salicylate, appraising results on patients who have been followed for at least eight months or longer, our failure group is 5.3 per cent. Our successes in that particular group, which totals 131, are 94.7 per cent.

DR. HARRY EAGLE, SURGEON, U. S. P. H. S.: The point has been raised as to the differentiation between reinfection and relapse in treated cases of early syphilis. The distinction is so difficult and the final decision is often so arbitrary that in the evaluation of a new therapeutic procedure any treated case in which dark field positive lesions develop within one to two years must be adjudged a treatment failure unless the evidence for reinfection is overwhelming. Those who are studying the intensive treatment of early syphilis are not necessarily protagonists of a particular procedure to the exclusion of all others. There are indications for highly intensive arsenotherapy and indications for more conservative treatment, and the correct procedure to be followed in the individual case must be decided by the physician on its own merits. There is no universally applicable method of choice. The best record will be given by a highly intensive procedure applied to a hospitalized patient. On the triweekly schedule I have described a certain proportion of patients will necessarily be lost, but the case holding record will be better than with routine weekly treatment continued for a year and a half. It is impossible to estimate precisely what the case holding record has been in our own study, because the duration of the scheduled treatment has deliberately been varied. Moreover, the proportion of patients completing their scheduled treatment has varied from as high as 90 per cent in some clinics to as low as 20 per cent in others. The degree to which patients

lapse is affected by many variables, a few of which are the type of patient, the efficiency of the social service workers and the quality of the medical care in the clinic itself. On a triweekly schedule more patients will receive an adequate amount of treatment than is the case with a weekly schedule but less than with a schedule involving hospitalization. In analyzing our results, no attempt was made to distinguish between the efficacy of the various types of bismuth preparation. Eighty per cent of the patients received bismuth subsalicylate and more than 90 per cent of those received 0.2 Gm. per weekly injection. Our experimental data indicate that, except for a possible slight superiority of an oil soluble preparation, there is but little difference in the therapeutic efficacy of the several types of bismuth preparations in current use.

DR. JEROME K. FISHER, New York: I realize that a paper as pessimistic as ours doesn't leave much room for comment. With the advent of penicillin and the extensive use of phenarsine compounds in intensive treatment of early syphilis, you have likely heard the swan song of arsphenamine. Our report has been based on all the cases, and those include the cases in which we gave only 1.5 Gm. The treatment of the cases in the sixth variation of our plan, all of which we have followed for six months or longer, has been 100 per cent effective. Our study showed that not all patients require the same amount of arsphenamine. In our early studies we had secondary cases that cleared completely and have been negative for over two years with 1.5 Gm. of arsphenamine. In our later group we had 2 seronegative primary cases in which 3.2 and 3.4 Gm. of arsphenamine were administered in six days which later became seropositive, with lesions and spirochetes recovered. Another fact brought out in our paper is that the largest doses of arsphenamine can be given in the first few days of treatment when the patient is in the best condition. That was the reason for the reversing of our schedule, so that in the allotted time, should a patient be ill, he would have the greatest quantity in his system. We retreated 18 patients. None of these have been included in the present report as having a second course of treatment or have been entered into any of the calculations. Of those 18 cases, all but 1 presented a Herxheimer reaction on the first day of the second course of treatment. In 8 of them the temperature ranged from 102 to 104 F. The paper, although unfavorable so far as the outcome of the use of arsphenamine is concerned, offers a great deal of other information, which unfortunately Dr. Cannon did not have time to include. I think that this will be of value in estimating other plans of intensive treatment, perhaps with penicillin.

DR. EVAN W. THOMAS, New York: With reference to reinfection and relapses, I agree heartily with Dr. Eagle that we must be very conservative. Of the relapses listed in the table which I showed, 12 were seronegative at the time they reappeared with dark field positive lesions. Those, I presume, might be listed as reinfections. However, we have other patients who were followed for thirty months or more. These patients came in with dark field positive lesions after they had been negative for over twenty-six months. They gave histories of promiscuous exposures. They were undoubtedly reinfections, but they were not seronegative at the time they came back. When I discussed the relapses and reinfections in my series, there was not agreement in every case. If you permit any particular person to decide which is a relapse and which is a reinfection, you may get into trouble. I was interested in what Dr. Bruyere said about the age groups. I wonder if it isn't possible that the much higher incidence of relapses in the younger age group is due to the fact that in the younger age group there were many more reinfections than there were in the old age group. It seems to me that is the most plausible explanation. It is exceedingly difficult to get a high follow-up percentage when you deal with Harlem patients in New York City. Nothing caused us such trouble or gave so much work as that follow-up. We still have under observation about 55 per cent of the patients treated in 1940, which I think is extraordinary for New York City. Of this last group only something like 53 per cent were followed over six months. We are now treating many Dutch, Scandinavian and English sailors. It is impossible, no matter what the follow-up system may be, to follow those patients.

MASSIVE ARSENOTHERAPY FOR SYPHILIS

UNITED STATES PUBLIC HEALTH SERVICE
EVALUATION

COOPERATING CLINICS OF NEW YORK AND MIDWESTERN GROUPS

Since the first experiments with massive arsenotherapy for syphilis using neoarsphenamine by slow intravenous drip, many methods of intensive treatment have been developed. The present study is concerned with a group of 4,351 intensive treatments for early syphilis contributed to the U. S. Public Health Service Field Study of Massive Arsenotherapy by the twenty-two cooperating clinics listed in table 1. This group of patients is limited to cases in the first four years of infection with or without active manifestations, treated dur-

ing the period 1933-1943 inclusive. However, the analysis of results deals only with cases in which there was active evidence of primary or secondary syphilis. Six different schemes of treatment were employed, as shown in table 2.

The follow-up observation on the cases studied was far from complete, but it was adequate for purposes of analysis. As shown in table 3, 18 per cent of the cases were not seen after discharge from the hospital, two thirds were not seen more than one year after treatment, and 85 per cent were not followed beyond the second year.¹ From the point of view of analysis of treatment results as affected by the adequacy of follow-up, it is of interest to note that only half of the secondary recurrences observed occurred in the first six months

Prepared under the direction of Miss Lida J. Usilton, Principal Statistician, with the assistance of Dr. Paul T. Bruyere and Mrs. Martha C. Bruyere, Statistical Section, Venereal Disease Division, U. S. Public Health Service.

Surgeon David C. Elliott, U. S. Public Health Service, was responsible for the promotion, organization, and carrying through of this cooperative endeavor, reporting in *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION*, Oct. 4, 1941, page 1169, the early progress on results of massive arsenotherapy for syphilis for the Midwestern and New York groups.

1. A considerable part of the cases were treated in 1942 and 1943 and hence could not have been observed as long as two years.

after treatment, and that as many as 12 per cent occurred more than one year after treatment.

In evaluating the results obtained, four broad groups were defined as "final outcomes": 1. A case negative for at least three months when last seen was considered to have experienced a "satisfactory result." 2. A case still positive or fluctuating when last seen a year or more after treatment was considered to be "serologically fast." (A fluctuating case was defined to be 1 in which the serologic test on the blood had been negative at some time after treatment, but never for as long as three consecutive months, and had subsequently become posi-

methods, such examinations were reported for too small a proportion of the cases.

For each treatment method included in the study, a greater percentage of satisfactory results was obtained among primary cases than among secondary cases. The percentages are given in table 4. Likewise, among

tive. The last observation might be either positive or negative.) 3. A case positive or fluctuating at last observation which had previously fulfilled the criteria for satisfactory result was considered to be a "serologic relapse." 4. A case experiencing relapsing secondary syphilis was considered to be a "clinical relapse." As far as possible, reinfections were excluded from this last category by means of the following criteria: completion of the prescribed course of treatment; blood negative to all serologic tests on two consecutive observations at least one month apart following completion of treatment; new lesion, not typical of recurrence, appearing prior to a serologic relapse. Spinal fluid test results could not be used in defining the final results as listed, because of the fact that, for several of the treatment

patients with secondary syphilis there developed more serologically fast cases, serologic relapses and clinical relapses proportionally than among primary cases. An average of 85.7 per cent satisfactory results was obtained in primary syphilis as opposed to 70.4 per cent in secondary syphilis. Six and four tenths per cent of the primary cases exhibited clinical relapse and 13.1 per cent of the secondary cases.

In comparing the several methods of treatment it was found that, although the differences in results from one treatment to another were not great, nevertheless not all of them can be ascribed to chance. In general, excluding the original slow drip with neosarsphenamine, which was found by its authors to be too reactive, the best results were obtained through the use of multiple injections of mapharsen combined with typhoid vaccine. Least effective, both in inducing satisfactory results and in preventing clinical relapses, were multiple injections of arsphenamine. However, when the material was

analyzed by amount of arsenical given (table 7) there were indications that the poor results obtained with this method may have been due to insufficient dosage.

The therapeutic results, then, that can be expected from present methods of massive arsenotherapy are at best about 85 to 90 per cent "cure" among cases in which treatment is started in the primary stage of the disease and 70 per cent among cases in which treatment

is started in the secondary stage. Primary cases show about 5 to 6 per cent clinical relapse, and secondary cases from 10 to 13 per cent. Perhaps as grave a consideration as the frequency of clinical relapses is the 8 per cent of primary cases and the 15 to 20 per cent of secondary cases that either remain serologically positive or show a serologic relapse, for any late manifestations of the disease which may occur will probably appear among these cases.

No significant differences were found between the results obtained in original infections and those obtained in reinfections. And, as shown in table 5, while the

reinfections showed both a larger percentage of satisfactory results and a smaller percentage of clinical relapses than did the relapses, the differences were not statistically significant. This is probably due to the small number of reinfections. As might be expected, primary syphilis, first infection, gave much better results than did relapses. However, there was no difference in the results obtained among previously untreated secondary infections and those obtained among patients with secondary manifestations occurring as a relapse after treatment, either routine or intensive in type.

In a considerable number of the cases treated by means of slow and rapid drip with mapharsen, blood specimens were examined at the time of treatment by means of the Kahn quantitative test. With both these methods of treatment it was found that cases whose

starting titer was 20 units or below had significantly more satisfactory results and fewer relapses than did cases with a starting titer higher than 20 units. These results are given in table 6.

In order to investigate the effect of the amount of arsenical administered, the results following each

TABLE 8.—Results Obtained with Massive Arsenotherapy in Early Syphilis, Showing the Estimated Percentage of Cases in Each Final Outcome Following Administration of Slow and Rapid Drip With Mapharsen With and Without Bismuth

Method of Treatment and Administration of Bismuth	Final Outcome			
	Satisfactory	Serologically Fast	Serologic Relapse	Clinical Relapse
Rapid drip, mapharsen				
Bismuth given	92.4	3.8	3.8
No bismuth given	70.4	8.4	8.4	12.8
Slow drip, mapharsen				
Bismuth given	72.3	10.9	3.1	13.7
No bismuth given	72.5	8.7	3.7	15.1

method of treatment were analyzed at various dosage levels. Table 7 presents the final outcome for each treatment scheme above and below the dosage levels which gave the largest differences. None of the differences are very great, and none are clearly significant. However, in nearly every case the differences are in the direction of better results with larger doses, and, when all treatments are combined, the difference is significant. In every instance more clinical relapses occurred among the smaller dosage groups.

Bismuth was administered in connection with the intensive treatment course in a portion of the cases in which either rapid or slow drip with mapharsen was given. Table 8 shows the results following these two treatments divided according to whether or not bismuth was given. It can be seen that with rapid drip the use of bismuth improved the results decidedly. Among the patients receiving this drug there were 92.4 per cent satisfactory results, compared with 70.4 per

TABLE 9.—Results Obtained with Massive Arsenotherapy in Early Syphilis, Showing the Estimated Percentage of Satisfactory Results and of Clinical Relapses for Each Method of Treatment, by Age at Time of Treatment

Method of Treatment	Per Cent Satisfactory Results		Per Cent Clinical Relapses	
	Under 25 Years of Age	25 Years of Age and Over	Under 25 Years of Age	25 Years of Age and Over
	Results	Results	Relapses	Relapses

Multiple injection, mapharsen	67.3	79.8	15.2	10.6
Multiple injection, mapharsen plus typhoid vaccine	68.6	84.2	9.7	2.7
Multiple injection, arsphenamine	58.4	74.1	25.0	9.5
Total, all methods	71.7	81.1	15.6	7.4

cent among those not receiving it. Conversely there were 12.8 per cent of clinical relapses among those not given bismuth and none among those who did get it.

Among the cases treated by slow drip, the results were not so clearcut. When all cases treated by this method were divided only according to whether or not bismuth was given, no significant differences were found. It was noted, however, that bismuth was used more frequently in the treatment of secondary syphilis-

than in primary syphilis and also that among primary cases it was given more frequently to those who were seropositive than to those who were seronegative.

Differences in response to syphilotherapy may be inherent in certain characteristics of the patient population, even though these characteristics are not in any way determined by the disease or its treatment. In seeking to investigate these points the results of intensive therapy were analyzed by race, sex and age.

With regard to age a very definite bias in favor of older patients was found. From table 9 it can be seen that 81.1 per cent of the older group reached a satisfactory outcome as opposed to 71.7 per cent of the younger patients, and whereas only 7.4 per cent of the

older patients experienced clinical relapses, 13.6 per cent of the younger ones did. These differences are too large to be ascribed to chance.

From table 10 it can be seen that there are both race and sex differences in the response to rapid treatment for syphilis. The proportion of satisfactory results obtained was consistently higher for the white race than for the nonwhite races and was also higher for males than for females. These differences remain significantly great when the four race-sex groups are considered separately: white males show a greater percentage of satisfactory results than nonwhite males; white females than nonwhite females; white males than white females; nonwhite males than nonwhite females.

The pattern of differences between the races and sexes is not so clearcut when considering the propor-

tion of clinical relapses as it is in the case of satisfactory results. The racial difference is still apparent, but there seems to be no difference between males and females. The clinical relapse rates are shown for race and sex in table 11. The nonwhite races show a significantly greater predisposition toward infectious relapse than does the white race for all treatments combined. From one sex to another, however, neither is there uniformity of direction in the differences from one treatment method to another nor is there a significant difference observable in all treatments combined.

The outstanding conclusion to be drawn from the foregoing analysis by patient population characteristics is that the group most resistant to treatment was that of young nonwhite females.

The present study is primarily concerned with the therapeutic efficacy of massive arsenotherapy, and the detailed analysis of reactions is not yet complete. The only data concerning treatment complications yet compiled are derived from a hand tabulation of the abstracts available on Aug. 1, 1943. At that time a search was made for cases showing evidence of encephalopathy which advanced to the point of convulsions. It was found that for all types of treatment combined there were 3.2 fatal encephalopathic reactions per thousand courses of treatment and 3.9 nonfatal, a total of 7.1 per thousand. No statistically significant differences could be demonstrated between individual clinics, methods of treatment, sexes or age groups. It was noted, however, that encephalopathy occurred more than twice as frequently among white persons as among nonwhites, and also that this type of reaction appeared to be more frequently fatal among white females than among white males or among nonwhites of either sex.

SUMMARY

1. The therapeutic results in a group of 4,351 massive arsenical treatments for syphilis have been studied.

2. It was found that the best results (excluding the highly reactive slow intravenous drip administration of nearsphenamine) followed the use of multiple syringe injection of mapharsen combined with typhoid vaccine.

3. The most effective massive arsenotherapy yields 85 to 90 per cent of satisfactory results in primary syphilis and 70 per cent in secondary syphilis.

4. About 5 to 6 per cent of the primary cases relapsed and 10 to 13 per cent of the secondary cases.

5. Patients treated when the titer of the Kahn quantitative test on the blood was 20 units or below experienced more frequent satisfactory results and fewer clinical relapses than did cases with a titer greater than 20 units.

6. Results were slightly better among patients receiving larger doses of arsenicals than among those receiving smaller doses.

7. The administration of bismuth during the period of treatment appeared to improve the results obtained.

8. The following differences in response to treatment were noted: Patients over 25 years of age responded better than those under 25; males responded better than females; whites responded better than nonwhites.

9. Least satisfactory results to treatment were obtained among young nonwhite females.

10. Acute encephalopathy was observed in 7.1 per thousand treatments. Of these 3.2 per thousand were fatal and 3.9 per thousand were followed by recovery. No difference could be demonstrated between treatments with regard to the frequency of this type of reaction.

THE INITIAL NEUROLOGIC AND PSYCHIATRIC SYNDROME OF PULMONARY GROWTH

MAJOR DR. A. M. MEERLOO, F.R.S.M.
OF THE ROYAL NETHERLAND ARMY

The syndrome described in this article demonstrates the fact that psychologic and somatic phenomena continually merge into one another, and that in pathology it is impossible to separate them.

It is not widely known that patients with a growth in the thoracic cavity often go in the first place to a neurologist. If one bears in mind that the initial complaint which gives rise to so serious a diagnosis is generally of vague neuralgic pains, it is important to consider the subject closely. The anamnesis is characteristic: the apparently healthy patient complains of spreading pains in the back or limbs. Intermittent neurologic signs and symptoms may be present or not. The patient is psychologically somewhat disturbed; his attention is rather closely fixed on his own pains. His intimates or his family doctor send him to the neurologist with a diagnosis of hysteria or neurosis. In the ordinary way the neurologist gives him psychotherapy. The next stage is the x-ray (in the initial phase this may not reveal anything immediately) and with the determination of the blood sedimentation rate the diagnosis is settled. It is however already possible to diagnose with fair certainty an intrathoracic growth before the x-ray gives a clear picture. If one finds, for example, sharp, spreading pains in the right arm and in the chest whether or not with hyperesthesia and abnormal tendon reflexes, and if at the same time the blood sedimentation rate is very much increased, a negative x-ray should not be relied on.

As a summary the following brief remarks should be added. In the case of my series of 9 patients covering a period of four years, it was not possible for the most part to attempt any pathologic research at the seat of the growth. The x-ray diagnosis and the clinical history as a whole were guaranties of the diagnosis. I saw still more of the same type of patient who had had only one consultation with a general practitioner. My impression is that these neurologic phenomena with an initial growth occur quite frequently—strictly speaking the metastases of intrathoracic tumors in the central nervous system come under the foregoing heading also. The pulmonary growth, especially, tends to produce metastases in the brain.

REPORT OF CASES

CASE 1.—A man aged 69 came for consultation because he had recently suffered from neuralgic pains in the right shoulder blade. His wife found him changed, more discontented and more irritable. His son, a doctor, considered that his father was always too ready to complain of his own ills. The neurologic examination was negative. The patient had not grown thinner. An x-ray examination revealed no abnormality in the spinal column or in the upper part of the lungs. Iontophoretic treatment did not relieve the pain. The patient went on a journey abroad in good spirits; on one occasion during the journey he brought up blood stained mucus, to which no attention was paid. With antineuralgic treatment the condition remained bearable. Six months after the first examination he suddenly brought up a lot of blood. The pain had meanwhile become much worse. The blood sedimentation rate increased, there was anemia, and the x-ray examination of the lungs showed a growth on the right hilus. Three months later the patient died.

CASE 2.—A man aged 57 suffered from spreading pains in the left arm. From time to time he had attacks of choking and of tiredness. He had been treated for neuralgic pains for some time, but latterly he had been more and more depressed, let himself go, became irritable; for this reason he was sent by his family doctor to the neurologist. The pains were usually at night, with a tingling feeling in the left hand. There were no motor or sensory disturbances, nor were there any typical centers of pain, apart from pressure on the ribs on the upper left side. The test for angina pectoris by the doctor was negative. A week later, after preliminary antineuralgic treatment, it appeared that the trachea was slightly displaced toward the right. This put us on the right track. The x-ray examination showed a large growth in the left half of the thorax which presumably issued from the first costal arch and pressed on nearly the whole left lung (sarcoma?). The blood sedimentation rate was 124 mm. Fourteen days later the tumor began to grow outward. In spite of x-ray therapy the patient died four months later.

CASE 3.—A man aged 56 suffered for many years from depression complicated by all kinds of neuralgic pains. As his chronic psychosis deteriorated and he became more violent owing to bitterness against his family, he was placed in a hospital for rest therapy. Examination revealed a slight anemia and a blood sedimentation rate of 60. Profiting by previous experiences and in view of the neuralgic pains in his chest and arms, an x-ray examination was made, with negative results. On these grounds it was decided to give a mild course of barbital, after which the patient felt psychologically much better. After two months he had a relapse, but his condition was still such that he could be nursed at home. Six months later the neuralgic pains were worse; they spread down the right arm and the right side of the thorax. The blood sedimentation rate was now 66. Eight months later came the first hemoptysis. When fresh x-ray films were taken a big pulmonary growth could be seen stretching from the right hilus. Nine months later the pains were more severe, especially at night, waves of pain running through the right hand and arm. There were no neurologic signs. In the tenth month there was slight paralysis in the right hand and arm, with edema of the hand, arm and head. A week later the patient died suddenly in his sleep.

CASE 4.—The patient's illness was announced by apparent sciatic pains, for which he was treated for over six months. The general health was good, but his family complained of his "hysterical" behavior; that is to say, he became more childish, tried to attract attention to his illness and claimed to suffer from more disturbances of functions than was actually the case. On examination a positive symptom of Lasègue was found with atrophy of the right calf, but—and this did not belong to the sciatic picture—a Babinski reflex of the soles of the feet and increased reflexes. At first both patient and family set themselves against clinical observation and lumbar puncture; and because the hysteriodpressive syndrome dominated, less attention was paid to neurologic signs. When the patient complained of more pain and neuralgic pains spread to the neck, the family agreed to clinical observation. Here too the x-ray revealed the diagnosis—a large growth at the hilus of the lung, probably growing in the spinal column, while at the third and fourth vertebrae of the neck there was actually a metastasis. The blood picture showed a simple anemia; the blood sedimentation rate was very high (110 after one hour).

CASE 5.—This case is very much akin to the preceding one. It also began with a sciatic syndrome, but it appeared easier to understand as there were metastases in the third, fourth and fifth lumbar from a bronchial carcinoma in the right upper lobe. Here also I was initially called into consultation for psychosis in connection with the sciatic symptoms. The man was childish, negative, depressed. The condition of the patient could not be ameliorated, and the diagnosis was confirmed by clinical examination after the doctor had really convinced the patient that it was necessary. The blood sedimentation point was 91 mm. in the first hour; there was no anemia. This patient also died one and one half months after admission in a state of cachexia.

CASE 6.—Here the diagnosis was more difficult, because the illness began clearly with pains and paralysis of the left arm. The patient was a man aged 67. At the first examination the reflexes in the paralyzed arm were increased, the pupils reacted rather slowly and there were indications of venereal disease in the anamnesis. For these reasons a thorough examination was considered necessary. At the clinical examination, however, no clues on which to base such an enquiry were found; blood and liquor reactions were negative, the x-ray film of the skull was normal, there were no abnormalities in ventricular pressure, blood pressure and renal functions were normal. We were faced with this problem: we had not yet considered the pathologic phenomena which he certainly showed, a blood sedimentation rate of 56 mm. and anemia. In the hospital the patient coughed up blood stained phlegm for the first time. An x-ray film of the lung was then taken and in the left apex of the lung a distinct pressure on the plexus had produced the phenomena already noted. The general condition of the patient remained good for a long time; there were no pathologic developments. A year passed before the patient died.

CASE 7.—A transport worker aged 52 had complained for over a year of rheumatic pains from the left elbow to the neck. The neurologist was consulted as to the possibility of a neuritis in the plexus. From time to time the finger tips were swollen and painful. On admission to the hospital it appeared that he also had pains in the upper part of his chest, and there was a sporadic coughing up of purulent sputum. A year later in another hospital rib section on account of empyema was performed. From the x-ray it appeared that the whole thorax was deeply shadowed and the radiologist suspected multiple tumors. After examination with iodized oil a complete stoppage was found in the left main bronchus at the bifurcation. There was anemia and a blood sedimentation rate of 87 mm. In the sputum there were no tubercle bacilli and no pneumococci, but many streptococci. Electrocardiographic examination was negative. One and a half months after admission to the hospital the patient died after the usual cachectic phenomena had appeared. At the autopsy it appeared that there was a carcinoma spreading from the left lung with metastases in the other lung, pleuritis carcinomatosa, and metastases in both kidneys, along the spinal column and in the liver.

The next 2 patients came to my notice in the confusion and excitement shortly after the German occupation, and for that reason the initial phenomena were all the more difficult to interpret.

CASE 8.—A woman aged 52, who had suffered in the bombardment of Rotterdam, was thereafter depressed and reserved, and five weeks later she came under my care for a sudden attack of asthma and traces of nervousness. She was first treated with sedatives, but after two weeks she had another attack of asthma. This gave rise to the taking of an x-ray film; a tumor of the lung was visible. She had a blood sedimentation rate of 110. The illness lasted six months, the psychosis remaining right up to the last.

CASE 9.—A man aged 44 was thrown against a wall by blast and afterward complained of pains in the shoulder and tingling in the fingers of the right hand. In the same way there was a certain dulness and apathy. The shoulder was x-rayed, but this produced no clues. The psychologic disintegration increased, neurologic symptoms slowly emerged and the reflexes decreased. The blood sedimentation rate was too high, and in view of earlier experiences a diagnosis of intrathoracic tumor was decided on. After six weeks' treatment the patient died very suddenly. He had shown no signs of lung symptoms. At the autopsy a primary lung carcinoma was revealed.

COMMENT

If we analyze the case histories of these people suffering from growths in or near the lung, who in the early stages come to the nerve specialist, we must direct our attention to the following facts:

The Psychologic Symptoms.—The psychiatrist ought to be able to establish the diagnosis of one or another

bodily process on the psychologic picture alone. There is unfortunately no typical psychologic process belonging to distinct organic lesions. There are, however, distinct syndromes which fasten suspicion on a bodily origin. Hysterical depression in the presenile period is significant, even before the onset of arteriosclerosis of the central nervous system. Among my 9 patients, in whom there was a certain negativism along with the syndrome, we must ascribe the psychologic symptoms to a toxic disorder of the central nervous system.

The Pain.—The pain was intense in all the cases. It was not only local but was spread over all parts of the body. This is in accordance with the toxic etiology of neuralgia, above all in those cases in which peripheral neurologic signs appeared. Here also factors connected with abnormal pressure on the sympathetic chain must be taken into account. One of my patients experienced the most intense pain a few days before it was clear from the congestion in the arm that there was pressure on the big vessels. In other cases (2 and 4) in which the tumor was already very big and the pain came later, we ought to have been able to establish the position, owing to the pressure on and erosion of the neighboring skeletal parts. The symptom of neuralgic pain pointed at least as often to a general disorder as to a specific involvement of the sensitive nerve tissue.

OTHER INITIAL SYMPTOMS OF GROWTH IN THE LUNG

Most growths in the lungs will show their true character without neurologic and psychologic clues. None of my patients had a growth beginning with hemoptysis, and among a few there was no instance of hemoptysis. It will more often happen that these patients die without any suspicion of pulmonary disease. A man aged 53 whom I saw in the last stages of his illness and who, because of his neurologic symptoms, paralysis of the arm and leg, was thought to be suffering from acute multiple sclerosis, died suddenly with hemoptysis, there being unfortunately no possibility of x-ray examination. In the initial stages also there was no cachexia among my patients. In all these cases there was an increased blood sedimentation rate from the first examination.

SUMMARY

Nine persons suffering from pulmonary growths consulted a psychiatrist and neurologist concerning their initial symptoms. Violent neuralgic pains with a negative hysterical depression and a raised blood sedimentation rate are a characteristic triad of symptoms demanding an immediate radiologic examination of the lungs. The difficulty of diagnosis lies in the initial psychologic interpretation of the symptoms.

Blood Transfusion in Modern Times.—Scientific use of transfusion in modern times may be traced to James Blundell (1790-1877). Having been much agitated over the loss of many patients through uncontrollable puerperal hemorrhage, he first experimented on animals which had seemingly bled to death and were revived by blood taken from animals of the same species. He then proceeded to investigate the possibilities of transfusion in cases of human hemorrhage. It should be noted here that before Blundell experiments were made by means of bladders fastened to quills; hypodermic needles were unknown. Blundell experimented with various instruments and developed in 1818 a syringe with a three way valve.—Gordon, Benjamin Lee: *The Romance of Medicine*, Philadelphia, F. A. Davis Company, 1944.

accelerated to a high velocity by a high potential difference as soon as they leave the cathode. They are then subjected to a magnetic (or electrostatic) field which acts as a condenser lens and controls the convergence of the electron rays irradiating the specimen. This beam passes through the object, through the magnetic (or electrostatic) objective lens and projector lens, finally to form the image on the fluorescent viewing screen or photographic plate. Electrons which pass through the object undeflected of course contribute to the brightness of the image; any electrons which are sufficiently deflected in the object so that they do not pass through a small aperture in the middle of the objective lens do not contribute to the brightness of the image. The image actually formed, therefore, is essentially a record of the amount of scattering of each electron pencil which traverses the object, and this scattering is to a first approximation proportional to the density times the thickness of matter traversed.

Fig. 1.—The electron microscope. On the left is a scale drawing and on the right a schematic diagram of the instrument showing the arrangement of lenses and the formation of images (After Anderson,⁴ fig. 1.)

Although the mechanism of image formation is different, electron micrographs may therefore be considered as analogous to x-ray pictures, the darkness and brightness depending on the thickness and density of the specimen. Electron pictures resemble x-ray pictures in another important respect, i. e. that the entire thickness of the usual specimen is in focus. The electron micrograph is thus a projection of the total thickness of the field under examination; this lack of a critical focal plane may cause the illusion of two separate objects, one of which overlies the other, appearing as parts of one object in the electron micrograph.

Since air itself scatters electrons, the interior of the electron microscope is kept at a high vacuum. The bacteria or other specimens are mounted, usually unstained, on a thin collodion film. Some shrinkage of parts of the bacterial cell, in particular the fluid or potentially fluid inner protoplasm, frequently occurs, as a result of the unavoidable drying; some distortion of the cell and its parts, due to drying against the mount, may also occur. We have not seen evidence of appreciable alteration of such small objects as bacteria by action of the electron beam itself.

THE STRUCTURE OF THE BACTERIAL CELL AS SHOWN BY THE ELECTRON MICROSCOPE

Bacteria are cells, with structurally differentiated parts. A cell wall, structurally distinct from the inner protoplasm, can be detected in electron pictures of each of the kinds of bacterium thus far adequately studied; this includes most micro-organisms pathogenic for man; cocci and rod forms, both gram positive and gram negative and spiral forms (e. g. figs. 2, 3, 4, 5, 6, 17, 22, 26 and 42). Differentiation within the inner protoplasm can be detected in many species in the form of dense spheroidal (fig. 7) or discoidal (fig. 8) granules or of less well defined areas of greater or lesser density (fig. 9). Spores form within the protoplasm of sporulating species (fig. 10); flagella are demonstrable on motile species. Nucleoprotein demonstrable chemically within the bacterial cell can be seen as localized under certain, but not all, conditions in what has been interpreted as a simple nucleus (fig. 11). Capsules in certain species such as the pneumococcus (fig. 12) and extracellular slime in others, such as *Streptococcus pyogenes*,⁵ are demonstrable outside the bacterial cell wall.

Bacterial Cell Wall and Inner Protoplasm.—The bacterial cell wall is in the solid state; it maintains its shape and position with relatively little alteration under conditions of drying or mechanical injury to the bacterial cell. The inner protoplasm with its limiting surface is either fluid or a gel which readily passes into the sol state, as is evidenced by the frequency with which the protoplasm appears shrunken away from the cell wall in dried specimens and escapes from the cell wall following injury of the bacterial cell. Bacterial cells may be broken by intense sonic vibration. After such treatment many of the cell walls appear as "ghosts"⁶ from which the inner protoplasm has escaped (fig. 2), and jagged lines of fracture of the cell wall may be found⁷ (fig. 13). Shrinkage or escape of inner protoplasm from the cell wall may be brought about by appropriate chemical reagents⁸ (figs. 14, 15 and 16). Intact cells and "ghosts" of autolyzed cells⁷ may be found together in preparations particularly from aging cultures (fig. 17).

In bacteria which are not quite completely divided, and in those which form chains, such as *Streptococcus pyogenes* (fig. 18) or clusters such as *Staphylococcus aureus* (fig. 19), the bacterial cell walls can be seen to be continuous from cell to cell; a connecting strand of protoplasm may or may not be present between the adjacent cells according to the completeness and nature of the cell division.

Differentiations Detectable Within the Protoplasm.—The inner protoplasm itself may appear homogeneous in electron pictures. Or inhomogeneities may be apparent in the inner protoplasm, as in micrographs of strains of *Fusobacterium*,⁹ *Treponema pallidum* (fig. 7), *Mycobacterium tuberculosis*¹⁰ (fig. 21), *Corynebac-*

terium diphtheriae¹¹ (fig. 8) and others. These inhomogeneities in the inner protoplasm may be of several kinds. In *Fusobacterium* (fig. 20), for instance, certain areas of the protoplasm may be denser than other areas,⁹ and such characteristic differences may even be apparent in stained preparations¹² viewed with the light

Fig. 3.—*Staphylococcus aureus*. The light appearing cell walls are particularly clearly shown surrounding the dark inner protoplasm of three of the central cluster of four cells. Reduced from an electron micrograph with a magnification of 10,000 diameters.

microscope. In other species definite spheroidal or discoidal granules of high density may be seen within the protoplasm; such granules have been recorded notably with *Mycobacterium tuberculosis* (fig. 21), *Treponema pallidum* (fig. 7), *Corynebacterium diphtheriae* (fig. 8) and *Staphylococcus flavocyaneus*¹³ (fig. 11). The significance of these granules is not clear in most species. In *Staphylococcus flavocyaneus*, however, microchemical and cytologic evidence¹³ strongly suggests the interpretation of these protoplasmic granules as simple nuclei; it seems probable that a similar interpretation may become appropriate for protoplasmic granules in other species, but this question had best be left open at the present, pending further evidence.

Fig. 4.—*Neisseria gonorrhoeae*. Two diplococcus pairs are intact; one pair is cytolized. Magnification 11,000 diameters. Reproduced through courtesy of Dr. H. E. Morton.

Inhomogeneities in the bacterial protoplasm may also be produced as artefacts due to coagulation, drying or partial cytolysis, as is of course obvious. Such artefacts

are more easily produced in the inner protoplasm than in the cell wall, because of the greater fluidity of the protoplasm. Knaysi¹⁴ has demonstrated that in ordinary bacteriologic specimens (viewed with the light microscope) it is only the inner protoplasm and its limiting membrane which are stained and visible. The cell wall is unstained and invisible unless prepared by special mordant and staining technic. Cell wall and protoplast with protoplasmic membrane are shown particularly clearly in figure 22.¹⁵

The Capsule.—The pneumococcus capsule has been demonstrated in electron micrographs¹⁶ (fig. 12) as a gel of low density outside of and closely enveloping the cell wall, the cell wall in turn enveloping the bacterial protoplasm with its outer limiting membrane. In the specific capsular swelling reaction the interstices of this capsule are permeated by rabbit immune serum; increase in the thickness and density of the capsule results¹⁷ (figs. 23 and 24).

Fig. 8.—*Corynebacterium diphtheriae*. Discoidal dense granules can be seen near ends of the cells. The protoplasm is shrunken away from the cell walls of several cells. Reduced from an electron micrograph with a magnification of 26,500 diameters. Courtesy of Dr. H. E. Morton.

Flagella.—Flagella are beautifully shown in electron micrographs of motile bacterial species without the necessity of using any mordant or stain. These flagella may occur singly, as on cells of *Vibrio cholerae*¹⁸ (figs. 14, 15 and 16), may occur all around the bacterial cell, as is the case with *Eberthella typhosa*¹⁹ (fig. 25) or *Clostridium tetani* (figs. 17, 26 and 27), or may occur in tufts, as is the case on cells of *Treponema pallidum* (figs. 6, 7 and 28). *Treponema*

Bact.* **42**: 395-409 [Sept.] 1941) has shown that in locomotion the flagella of each typhoid bacillus are plated together to form a corkscrew shaped "tail," which is the actual locomotor organ.

BACTERIA—MUDD AND ANDERSON

564

pallidum was described as without flagella until flagella were demonstrated in electron micrographs.²⁰

Spores and Sporelike Bodies.—Spores form within the protoplasm of the cells of bacteria of the genus *Clostridium* (the tetanus gas gangrene group) and of the genus *Bacillus*,⁷ which includes *Bacillus anthracis*. In young cultures the protoplasm of the bacterial cells may appear homogeneous (fig. 26). In older cultures much of the protoplasm appears to be condensed into the spores (figs. 10 and 27), which appear as exceedingly dense bodies within a protoplasm of reduced density. Subsequently the spore-mother cell shrivels up (fig. 29) and the spore is freed (fig. 30).

Electron micrographs²¹ of *Treponema pallidum* in a number of instances have shown minute bodies of high density attached to the spirochetal cells (figs. 31 and 32); these dense bodies may be closely applied to the sides of the spirochetes or may be attached to the side of the spirochetal cell by short stalks or may be found free. These bodies have been described by a long series

Manouélian.²⁴ If this interpretation is correct, it might aid, as Ingraham has pointed out, in explaining puzzling aspects of latency, drug resistance and recurrence in syphilis.

Fig. 12—*Pneumococcus* type 111. Reproduced from Mudd, Hemmets and Anderson¹¹ (fig. 1). The delicate areola about each cell or diplococcus pair is the capsule. Reduced from an electron micrograph with a magnification of 11,000 diameters.

It is of interest to consider whether the structural differentiations thus far revealed by the electron microscope afford a clue to the nature of the organization

Fig. 10—*Bacillus anthracis*. Two chains of vegetative cells, spores appear to be forming in three cells of the lower chain, one extracellular spore is seen from the lower chain. Slightly reduced from an electron micrograph with a magnification of 3,340 diameters.

of investigators; the terms applied to them, "knospen" or "buds" (Meirowsky), "sporelike spherical bodies" (Noguchi), "granules spirochétogènes" (Manouélian), express the interpretation often explicitly made that these are asexual resting or resistant bodies like spores capable of reproducing asexually the normal spirochetal cell. The very impressive accumulation of evidence supporting this interpretation has been reviewed by Meirowsky²² and Ingraham²³ and more recently by

Fig. 17—*Clostridium tetani*, 10 day old culture. One intact cell is undergoing unequal division to produce a coccoid cell. The other cells are more or less cytolized. Slightly reduced from an electron micrograph with a magnification of 9,300 diameters.

underlying the amazingly diverse and intricate chemical processes which occur within the minute dimensions of the bacterial cell. *Streptococcus pyogenes*, for

instance, elaborates a characteristic type specific protein, M, whose locus is at least in part at the surface of the streptococcus cell wall;²⁵ the majority of strains thus far analyzed²⁶ possess a second type specific agglutigen T of unknown chemical composition; strains of *Streptococcus pyogenes* elaborate a carbohydrate C characteristic of the serologic group,²⁷ protein or nucleoprotein components which cross-react with proteins of streptococci of other groups and of pneumococci²⁸ and nucleic acids of both the d-ribose and desoxyribose types.²⁹ *Streptococcus pyogenes*, given the necessary growth accessories and amino acids,³⁰ elaborates the enzyme systems required for aerobic and anaerobic respiration. *Streptococcus pyogenes* in its mucoid phase secretes an extracellular mucoid material, hyaluronic acid,³¹ which appears to be identical with a polysaccharide of the mammalian umbilical cord, the vitreous humor³² and an interfibrillar substance of the corium. *Streptococcus pyogenes* produces at least three demonstrably distinct physiologically active metabolites which are antigenic: the erythrogenic or skin toxin,³³ the streptococcus hemolysin³⁴ (streptolysin) and fibrinolysin,³⁵ which, acting conjointly with a lytic agent in human serum,³⁶ causes lysis of human and rabbit fibrin. Certain strains at least of *Streptococcus pyogenes* elaborate an enzyme, hyaluronidase, capable of depolymerizing and hydrolysing hyaluronic acid;³⁷ this hyaluronidase is known as a "spreading factor" because of its action in facilitating the dissemination of foreign material, doubtless including bacteria and their products, in the corium.³⁸ *S. pyogenes* liberates a "lethal agent"³⁹ of small molecular size.

the minute structural units in the protoplasm of phage lysed *E. coli* cells by Luria, Delbrück and Anderson⁴² or of the thixotropic gel-like organization of the axoplasm of nerve cells of the squid by Richards, Steinback and Anderson⁴³ may afford first glimmers of light as to what the nature of this pattern of organization may ultimately prove to be.

THE MORPHOLOGY OF RICKETTSIAS AND PLEURO-PNEUMONIA-LIKE MICRO-ORGANISMS

Epidemic and endemic typhus fevers, the spotted fevers, Q fever and scrub typhus or tsutsugamushi disease are caused by pathogenic rickettsias. These are⁴⁴ "small, often pleomorphic, gram negative, bacterium-like organisms, living and multiplying in arthropod tissues, behaving as obligate intracellular parasites, and staining lightly with aniline dyes." *Rickettsia prowazeki*, the causal agent of typhus, in its most characteristic form appears as a minute diplobacillus, each member of the diploid form averaging about 0.6 by 0.3 micron.

The rickettsias may be regarded as intermediate in the biologic scale between bacteria and the viruses. Thus in size, shape and staining characteristics they are like little pleomorphic bacteria; they resemble the

viruses in their obligate intracellular parasitism. They may also "be regarded as intermediate in their degree of adaption to intracellular conditions, since they grow best in cells which are metabolizing slowly." For a fuller discussion the reader is referred to the review of Pinkerton.⁴⁴

The morphology of typical rickettsias has recently been studied and beautifully illustrated with electron micrographs by

Fig. 24—*Pneumococcus* type I treated for thirty seconds with undiluted homologous rabbit antiserum; more advanced stage of swelling than in figure 23. Magnification 19,200 diameters

Plotz, Smadel, Anderson and Chambers.⁴⁵ The essential findings have been confirmed by Weiss.⁴⁶ These electron pictures show that rickettsias (figs. 33, 34 and 35), like bacteria, are cells with a limiting cell wall clearly distinct from the inner protoplasm. The protoplasm of the rickettsial cells itself shows pronounced differences in density; the denser areas may be more or less sharply localized. Rickettsial cells are pleomorphic, i. e. the cells of a given preparation differ much in size and shape.

Another category of parasitic micro-organisms whose characteristics may be considered as intermediate between bacteria and viruses is the pleuropneumonia-like group. The literature has been reviewed by

Dienes and Smith^{48a} and by Hesselbrock and Foshay.^{48b} Although these forms may depart widely in structure and reproductive behavior from ordinary monomorphic conceptions of bacterial morphology, their organization is still essentially cellular. A pleomorphic strain of *Bacteroides funduliformis* is under electron microscopic study.^{48c}

MORPHOLOGY OF VIRUSES

The viruses are intracellular agents of disease which can be propagated only in the presence of cells that they parasitize. The viral infectious units, moreover, are too small to be resolved and in most cases even to be made visible by ordinary light. It has been natural therefore for many to suppose that viruses are essentially similar to one another in their physical and chemical nature. Other students of viruses, however, notably T. M. Rivers,⁴⁹ have for some years advanced reasons for concluding that viruses are heterogeneous and differ widely in nature among themselves. The electron microscope is providing clear morphologic evidence of the heterogeneity of viruses. Vaccinia elementary bodies,⁵⁰ as an example of the larger viruses,

Fig 29—*Clostridium sporogenes* cells from a three day culture. Nothing remains of the vegetative cells except "ghosts," to which peritrichous flagella remain attached, in one "ghost" is a spore. Slightly reduced from an electron micrograph with a magnification of 14,000 diameters.

have an essentially cellular organization resembling that of bacteria; viruses of intermediate size such as bacteriophage still possess structural differentiation;⁴² the smallest viruses apparently are giant molecules or minute crystals. A scale of dimensions is given in figure 37.

Animal Viruses.—The morphology of that category of viruses in which the elementary infectious units are largest, namely the psittacosis-lymphogranuloma trachoma group, has not yet been investigated with the electron microscope as far as we are aware. Such studies would be most desirable.

Vaccinia Elementary Bodies.—The morphology of the virus of vaccinia has been presented in clearest detail by Green, Anderson and Smadel,⁵¹ from whom the following is quoted:

⁴⁸ Smith, W. E., and Mudd, S. To be published.
⁴⁹ Rivers, T. M. Viruses and Virus Diseases (Lane Medical Lectures), Stanford University, Calif., Stanford University Press, 1939.
⁵⁰ Rivers, T. M. Virus Diseases, with Particular Reference to Vaccinia, from Virus Diseases by Members of the Rockefeller Institute for Medical Research, Ithaca, N. Y., Cornell University Press, 1943, pp. 331.

(Footnote's continued in the next column)

Elementary bodies of vaccinia when viewed by electron microscopy present a high degree of regularity of external outline and of internal form. The particles are almost rectangular in shape and usually possess five circumscribed areas

Fig 33—*Rickettsia prowazekii* from epidemic typhus. Reproduced through the courtesy of Dr. Leslie A. Chambers, Johnson Foundation for Medical Physics, University of Pennsylvania. Magnification 40,000 diameters.

which are more dense than the surrounding substance and hence appear darker in the electron micrograph. The central area of condensation in the elementary body is slightly larger than the others which are spread around it; their general arrangement suggests that of the five spots on dice.

Fig 34—*Rickettsia prowazekii* from murine typhus. Reproduced through the courtesy of Dr. L. A. Chambers. Reduced from an electron micrograph with a magnification of 40,000 diameters.

Elementary bodies which are joined by a narrow bridge of material of lighter density than the bodies themselves are not infrequently encountered. The general shape of the virus particles seems to resemble a brick (fig. 36).

⁵¹ Green, R. H., Anderson, T. F., and Smadel, J. E. Morphological Structure of the Virus of Vaccinia, *J. Exper. Med.* 75: 651-656 (June) 1942.

The elementary bodies may be cytolized by ten minutes' exposure to tenth normal sodium hydroxide. The limiting membranes of the elementary bodies remain after cytolysis as "ghosts." "Certain of the ghosts formed in this manner have ruptured; some have wedge shaped gaps in their surfaces and others show substance streaming from them."

Fig 35—*Rickettsia* (*Dermacentroxenus rickettsi*) from Rocky Mountain spotted fever. Reproduced through the courtesy of Dr L. A. Chambers. Reduced from an electron micrograph with a magnification of 40,000 diameters.

Elementary bodies of vaccinia thus resemble bacteria in having an essentially cellular organization. In their complex chemical and antigenic composition⁵⁰ they also resemble bacteria.

Influenza, Equine Encephalomyelitis, Papilloma and Foot and Mouth Disease Virus Particles.—Identifica-

Fig 36—*Vaccinia* elementary bodies. Reproduced through the courtesy of Drs R. H. Green, T. F. Anderson and J. E. Smadel.⁵¹ The polyhedral bodies are often joined to form diploids or short chains by the continuity of their limiting surface. Reduced from an electron micrograph with a magnification of 45,000 diameters.

tion and characterization of the elementary infectious units causing virus diseases in man and animals has been rendered very difficult by the fact that until recently the sole sources of such virus particles have been suspensions prepared from infected somatic tissues. Introduction of the method of propagation of virus in

the chorioallantoic sac⁵² of the embryonated hen's egg with recovery of virus from the chorioallantoic fluid has ameliorated but not removed this difficulty of distinguishing with certainty between infectious agent, tissue detritus and other noninfectious material.⁵³

Moreover, the physical methods employed for separation of viruses, such as ultrafiltration, ultracentrifugation, electrophoresis and diffusion measurements, are complex and contain possibilities of error which may be incompletely explored. It is not surprising, then, that the morphology of very few viruses of human and other animal diseases may as yet be described without reservation.

Fig 37—Comparative sizes of viruses, revised as of June 1944 by W. M. Stauley.⁵ (fig. 6)

Early studies of the infectious agent of influenza derived from lung tissue led to the conclusion that the diameter of the infectious unit was between 80 and 120 millimicrons. The nature of influenza virus was

⁵² Woodruff, A. M., and Goodpasture, E. W. The Susceptibility of the Chorioallantoic Membrane of Chick Embryos to Infection with the Fowl Pox Virus, *Am J Path* 7: 209-222 (May) 1931. Scott, J. P. Swine Influenza, 13th International Veterinary Congress, Zurich Inter-laken 1: 479-490, 1938. Henle, W., and Chambers, L. A. The Serological Activity of Extraembryonic Fluids of Chick Infected with Virus of Influenza A, *Proc Soc Exper Biol & Med* 46: 713-717 (April) 1941. Burnet, F. M. Growth of Influenza Virus in the Allantoic Cavity of the Chick Embryo, *Australian J Exper Biol & Med* 19: 291-295 (Dec) 1941. Nigg, C., Wilson, D. E., and Crowley, J. H. Studies on the Cultivation of Influenza Virus, *Am J Hyg*, Sect B 34: 138-147 (Nov) 1941.

⁵³ A word of caution is perhaps in order with respect to virus strains propagated within the chorioallantoic sac. Burnet and Bull (Changes in Influenza Virus Associated with Adaptation to Passage in Chick Embryos, *Australian J Exper Biol & Med* 21: 55-69 [June] 1943) have shown that the virus of influenza A, isolated from human cases, on propagation *in ovo* undergoes phase variation. The adapted or derivative (D) phase differs appreciably in a number of respects from the original (O) phase. Only the derivative phase can be propagated in the allantoic cavity.

reinvestigated by Chambers and Henle⁵⁴ and by Chambers, Henle, Lauffer and Anderson,⁵⁵ using both suspensions from influenzal lungs and suspensions of virus obtained from the allantoic fluid of chick embryos infected with influenzal virus. The results of sedimentation experiments in the angle ultracentrifuge, together with other observations, seemed to indicate the elementary infectious particles of influenza to be only about 11 millimicrons in diameter. Subsequent work, however, revealed an unreckoned complication dependent on convection currents in the angle centrifuge⁵⁶. Critical reinvestigations of the infectious units of human influenza viruses A and B by Taylor, Sharp and their collaborators,⁵⁷ by Stanley⁵⁸ and by Friedewald and Pickels⁵⁹ have recently indicated in each case that the unit infectious particles of human influenza virus have diameters within the range originally estimated. Similar findings are obtained by Taylor, Sharp, McLean, the Beards, Dingle and Feller⁶⁰ for the virus of swine influenza.

Electron micrographs recently made in the RCA laboratories in Princeton of preparations of PR 8 strain (type A) and Lee strain (type B) human influenza virus, purified and concentrated from infectious extra-embryonic fluids of chick embryos by means of differ-

Fig 38—Virus of human influenza type A, PR 8 strain. Reproduced through the courtesy of Dr Wendell M Stanley. Reduced from an electron micrograph with a magnification of 30,000 diameters.

ential centrifugation, are shown in figures 38 and 39. These may be characterized as spheres with a diameter of about 100 millimicrons. Recent analysis by Knight^{59b} in Stanley's laboratory indicates, however, that even these infectious purified virus particles have measurable

amounts of normal chick components associated with them, possibly adsorbed to their surfaces.

Infectious particles have recently been separated by Taylor and his collaborators⁶⁰ from the tissue of chick embryos infected with the virus of equine encephalomyelitis (eastern strain). These particles are described by the authors as containing 54 per cent fat solvent

Fig 42—Bacteriophage particles, α strain, attached to cells of *Escherichia coli*. Reduced from an electron micrograph with a magnification of 17,500 diameters.

extractable material, 4 per cent carbohydrate and the remainder nucleoprotein of the ribose type. Electron micrographs show these particles to be of considerable uniformity; they are described by the authors as "probably spherical in shape, constituted peripherally of a substance the limits of which are ill defined in the micrographs in the absence of special treatment." The centers of these particles appear to be denser than the peripheries. After appropriate treatment with isotonic solution of three chlorides diluted 1:3 with 0.25 per cent calcium chloride the peripheral portion of the particles becomes darker and sharper. The authors give the mean diameter of the particles of vague outline as 40.2 millimicrons, that of the particles after treatment with calcium chloride as 47.5 millimicrons.

It may be considered that the observations summarized suggest a differentiation of these virus infec-

Fig 43—*Escherichia coli* plus virus γ , twenty three minutes' contact. A bacterium immediately after lysis showing protoplasmic granules and several hundred particles of virus. Reproduced from Luria, Delbrück and Anderson⁴² (fig. 5). Reduced from an electron micrograph with a magnification of 20,000 diameters.

tious units into a surface material enclosing an inner material of different composition. If all the foregoing observations are confirmed and the particles are proved

60. Taylor, A. R.; Sharp, D. G.; Beard, D., and Beard, J. W. Isolation and Properties of the Equine Encephalomyelitis Virus (Eastern Strain), *J. Infect. Dis.* 72: 31-41 (Jan.-Feb.) 1943. beyond question to be actual infectious units of the virus, it would appear that these and similar virus units may represent the simplest organization⁶¹ of life thus far described.

Electron micrographs of similar character have been published by the same authors⁶² for the virus of the

Fig. 45.—Virus of cucumber mosaic 4. Reproduced from Stanley and Anderson⁷² (fig. 15). Reduced from an electron micrograph with a magnification of 20,000 diameters.

western strain of equine encephalomyelitis. The authors conclude that "the western strain equine encephalomyelitis virus is a spherical or disk shaped particle of

density surrounded by an enveloping material of less density." The same authors have reported similar findings for the virus of rabbit papillomatosis.⁶³

Glaser and Stanley⁶⁴ have separated purified nucleoprotein particles from the blood of silkworms diseased with silkworm jaundice. Electron micrographs and ultracentrifugation data show these particles to be spheres with a diameter of the order of 10 millimicrons and molecular weight of about 300,000. Preparations of these purified particles reproduce the disease in very high dilution; despite this and other suggestive evidence, the authors refrain from drawing the conclusion that these particles are to be considered with certainty as being the active disease agent.

Electron micrographs of particles believed by the authors to be the virus of foot and mouth disease have been published by von Ardenne and Pyl.⁶⁵

Bacterial Viruses.—The physical nature of bacterial viruses (bacteriophage particles) until the introduction of the electron microscope could only be inferred from

Fig. 48.—*Eberthella typhosa* sensitized with 1:8 antityphoid rabbit serum; one hundred and five seconds' contact with serum. Flagella and cell somatic surfaces are coated with protein from the specific antiserum. Reduced from an electron micrograph with a magnification of 27,000 diameters.

Fig. 47.—*Eberthella typhosa* sensitized with 1:4 antityphoid rabbit serum; thirty seconds' contact with serum. The flagella are thickened and darkened by deposition of antibody globulin on their surfaces; the bacterial cell walls also have a film of protein from the specific antiserum. Clear spaces due to shrinkage of the inner protoplasm on drying separate the protoplasmic membrane from the serum-sensitized cell walls. Reduced from an electron micrograph with a magnification of 27,000 diameters.

approximately 40 millimicrons in diameter. Electron micrographic images reveal an internal structure characterized by a round or oval region of relatively high

studies by indirect methods. Investigations prior to 1941 have been reviewed by Krueger and Scribner.⁶⁶ Investigations of bacterial viruses with the aid of the electron microscope have been published by Ruska,⁶⁷ Kausche and Pfankuch,⁶⁸ Luria and Anderson,⁶⁹ Luria, Delbrück and Anderson⁴² and by Baylor, Severens and Clark.⁷⁰

61. By "organization," in the sense used, is meant differentiation and localization of components of structure which are not merely structural units or "building stones" of a single molecule.

62. Sharp, D. G.; Taylor, A. R.; Beard, D., and Beard, J. W.: Electron Micrography of the Western Strain Equine Encephalomyelitis Virus, *Proc. Soc. Exper. Biol. & Med.* **51**: 206-207 (Nov.) 1942.

The definitive studies of phage structure thus far are those of Luria, Delbrück and Anderson.⁷¹ These concern particularly two strains of coli phage, α and γ , which are propagated on the same strain of *E. coli*; the same bacteria then produce particles of type α if acted on by virus α , and particles of type γ if acted on by virus γ . Both types of phage particle, amazingly, prove to be structurally differentiated "sperm shaped" bodies.

"The particles of virus α have a round head, 45 to 50 millimicrons in diameter and uniformly dark in the micrographs; that means uniformly scattering for 60 kilovolt electrons (fig. 40). To this round head is attached a tail about 150 millimicrons long and not more than 10 to 15 millimicrons thick. The tail appears either straight or slightly curved.

"The particles of virus γ present a very peculiar aspect (fig. 41). To an oval head, 65 by 80 millimicrons, a straight tail, 120 millimicrons long and 20 millimicrons thick, is attached at one of the narrow poles. The head always shows a structure consisting of light and dark areas. The structure, although striking enough to make the particles immediately recognizable, is quite variable. Four frequent configurations can be described schematically as X shaped, Z shaped, inverted Z shaped and diplococcus shaped."

The authors believe that the dark parts represent regions of greater thickness in the dried particle. "It is possible that the particles in the native state are oval, but on drying the more aqueous parts collapse, while the solid parts retain more scattering material, which forms the dark areas of the heads."

Particles of another coli-virus are round, 50 to 60 millimicrons in diameter, and no tail can be seen.⁷² Particles of a staphylococcus virus have a head about 100 millimicrons in diameter and a tail about 200 millimicrons long.⁷²

In later work Anderson⁷³ has demonstrated that the heads of coliphage particles may be injured by sonic vibration or by ultraviolet irradiation, so as to permit escape of the dense material of the head, leaving its surrounding membrane as a "ghost" to which the tail is still attached.

Plant Viruses.—W. M. Stanley in 1935 announced the preparation of the virus causing mosaic disease in tobacco plants in the form of a crystalline nucleoprotein. Subsequent work has confirmed and greatly extended this discovery. The unit particle of this virus is now well established to be a rod shaped nucleoprotein "macromolecule" whose diameter is about 15 millimicrons and whose length is about 280 millimicrons. These molecules tend to aggregate end to end and side to side to form crystal-like structures of two dimensional regularity (fig. 44). Analysis by x-ray diffraction⁷⁴ has shown that the unit particles or molecules of the tobacco mosaic virus nucleoprotein themselves have a definite internal architecture that is due to regular and periodic arrangement of the structural units of which the macromolecule is composed.

Minute amounts of these crystalline macromolecules properly inoculated into susceptible plants of many species are infective; the virus is capable of indefinite propagation in diseased plants; modifications of the virus have been observed to occur in certain host plants and the variant virus strains have been shown to have

demonstrable chemical differences from the parent strain.⁷⁵ Tobacco mosaic virus thus possesses the properties of reproduction and adaptation, two attributes which have heretofore been considered as distinctively characteristic of living systems; whether or not a crystalline nucleoprotein molecule can be considered to be alive, however, raises questions which cannot profitably be considered here.

Other plant viruses, such as the cucumber mosaic virus (fig. 45), have been shown to be essentially similar to that of tobacco mosaic disease. The virus of tomato bushy stunt (fig. 46),⁷⁴ on the other hand, has been shown to consist of spherical particles about 26 millimicrons in diameter and that of tobacco necrosis⁷⁵ of essentially spherical particles about 20 millimicrons in diameter.

NOTE.—The second instalment of this paper, by Dr. Mudd, will appear in next week's issue of THE JOURNAL.

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

AUSTIN E. SMITH, M.D., Secretary.

ISO-PAR.—A mixture of water insoluble isoparaffinic acids partially neutralized with hydroxybenzyl-dialiphatic amines. The water insoluble isoparaffinic acids are obtained by oxidation of petroleum hydrocarbons by the passage of a current of oxygen under pressure at an elevated temperature in the presence of a metallic catalyst. The water insoluble monocarboxylic and dicarboxylic acids with from 6 to 16 carbon atoms are separated and purified by fractional distillation. The hydroxybenzyl-dialiphatic amines are combined directly with the isoparaffinic acids or in a suitable solvent. The latter is then removed by distillation.

Actions and Uses.—Unguentum Iso-Par is for external use only. It should not be covered with thick tight bandaging, since irritation may result from this type of dressing. It is said to be of value in the treatment of pruritus ani and vaginae, mycotic infections of the hand and feet and eczemas of the ear and certain skin allergic manifestations. This ointment is stimulating, lowers the levels of irritability of the skin and is in varying degrees bactericidal and fungicidal.

Dosage.—It should be applied with a rubber finger stall, a small wad of absorbent cotton or gauze, or other convenient applicator, since it possesses an odor which may be objectionable if it persists on the fingers. The first applications may cause a temporary burning sensation, but this disappears later. The ointment should be applied to the affected area in the evening before retiring and again in the morning; if necessary, it may be applied more frequently. It is claimed that the majority of cases will show evidence of response within three to five days, possibly up to two weeks. If by that time relief is not obtained, some other form of treatment should be substituted.

Tests and Standards.—

Iso Par is a viscid, dark brown, oily liquid having a characteristic odor of burnt petroleum. It is immiscible with water; freely miscible with alcohol, volatile oil and fixed oil. The specific gravity is from 0.970 to 0.980 at 25°C.

Place about 2 cc. of iso-par in a glass stoppered cylinder, add 20 cc. of water, shake the contents for five minutes, filter through moistened paper and divide into two portions; to one portion add two drops of methyl red test solution; a distinct red color persists; to the other portion add two drops of thymol blue test solution; a distinct yellow color persists.

MEDICAL CHEMICALS

Unguentum Iso-Par: 14 Gm., 28.5 Gm., 114 Gm. and 454 Gm. jars. Contains Iso-Par 17 per cent and titanium dioxide 4 per cent in an ointment base consisting of beeswax, cetyl alcohol, lanolin and petrolatum.

PUNISHMENT FOR VENEREAL DISEASE IN THE ARMED FORCES ENDED BY CONGRESS

The signature of the President has now enacted into law S. 1250, an act to repeal section 2 of the act approved May 17, 1926, which provides for the forfeiture of pay of persons in the military and naval service of the United States who are absent from duty on account of the direct effects of venereal disease due to misconduct, and to amend Veteran's Regulation No. 10, as amended to define line of duty and misconduct for pension and compensation purposes. S. 1250 was passed unanimously by the Senate on July 3, 1943 and by the House of Representatives on Sept. 11, 1944.

The new law abolishes all punishment for the acquisition of venereal disease, which is now "in line of duty" and is not "due to wilful misconduct," provided only that the infected person complies with Army or Navy regulations requiring him to report and receive appropriate treatment, and provided further that at the time of infection he was neither avoiding duty by desertion or absence without leave, nor confined under sentence of court martial or civil court. Failure to report a venereal infection (i. e., concealment) remains punishable by court martial or other disciplinary action at the discretion of the commanding officer (A-R 40-210, par. 23e). Moreover, the new law provides that, with the exceptions noted, veterans who have acquired venereal disease in line of duty are eligible for pension and compensation benefits if disability results.

The law is not retroactive, and a claim heretofore disallowed by reason of misconduct or line of duty requirement may not be revived; but benefits may be payable on the basis of a new claim filed hereafter in such form as may be prescribed by the Administrator of Veteran's Affairs.

The abolition of punishment for venereal disease was strongly urged by the Surgeon General, U. S. Army, by the Subcommittee on Venereal Diseases, National

Research Council, and by other authorities in social hygiene and preventive medicine. Modern public health opinion is convinced that fear of punishment does not prevent exposure to venereal disease and that punitive measures promote concealment, self treatment and treatment by nonmilitary personnel. Concealment, in turn, results in continued spread of disease in the civilian population and in the armed forces themselves, and in special military hazards, as in aviators. Punishment is discriminatory, in that military personnel may be penalized not for the fact of infection but for failure to respond to treatment and for various other extraneous reasons.

Under the new law just passed, the soldier or sailor infected with a venereal disease is now on the same status as one with any other acute infectious disease. The armed forces of the United States join those of Canada and France in the abolition of punishment for illness. A public health step of the first importance has been taken.

CHRONIC GASTRITIS

In his address as retiring president of the Connecticut State Medical Society, Smith¹ discusses research on experimental gastric cancer, its background and progress. One of the stumbling blocks in the studies of human gastric cancer is chronic gastritis.

Schindler² holds that gastroscopy has brought convincing proof of the frequency and significance of chronic gastritis, which he divides into superficial, atrophic and hypertrophic varieties. He also reports that the histology of chronic gastritis has been established by a method of taking biopsies from the gastric wall without ligatures or clamps. "If a normal mucosa is found gastroscopically, a normal microscopic picture is usually seen also."

Schindler's remarkable work with the flexible gastroscope receives complete and enthusiastic endorsement by Crohn,³ who characterizes "antral gastritis" as a clinical and morphologic entity, a conclusion with which Schindler does not agree. "Gastric function in all types of gastritis is so irregular and equivocal that it cannot be the basis of classification." In gastric cancer there is frequently a long story of gastric distress; Schindler refers to modern statistics as proving that patients with chronic gastritis are three times more prone to gastric carcinoma than healthy persons.

This view, as well as current interpretations of chronic gastritis, is not supported by the morphologic

studies of the mucous membrane of the stomach at various ages by Guiss and Stewart.⁴ With regard to the literature on the endoscopic aspects of chronic gastritis they say "As yet we have been unable to discover a fully correlated pathologic study made on gastroscopically diagnosed cases, nor have we had the opportunity to study enough such cases to enable us to draw any conclusions ourselves as to whether the gastroscopic diagnosis can be substantiated pathologically with uniformity."

According to Guiss and Stewart, chronic atrophic gastritis is characterized morphologically by atrophy of the mucous membrane, by increase in lymphoid tissue and in interstitial infiltration, by the transformation of the epithelial lining into the so-called intestinal or simplified type, by pyloric gland heterotopia and by increase in connective tissue. Such changes were found commonly after the fortieth year in 66 per cent of cases of death from extragastric cancer, in 82 per cent of apparently normal stomachs and in 97 per cent of deaths from gastric cancer. The inference drawn from these extensive morphologic observations is that the frequency of chronic gastritis with advancing age really may not have any other relationship to gastric cancer than intensification of gastritis by the cancer. Does early carcinoma of the stomach occur without gastritic changes?

Needed advancement in the understanding of the causation and significance of the morphologic processes of chronic gastritis will depend largely on organized cooperation by investigators concerned with the various phases of the problem. On the clinician, the gastroscopist, the radiologist and the pathologist falls the difficult task of securing adequate human material for cooperative study.

TOXICITY OF RANCID LARD

Physiologists have long recognized that rancid fats are nutritionally deleterious. According to Burr and Barnes¹ of the University of Minnesota the apparent toxic effects of rancid products are due mainly to an induced vitamin deficiency. Mixed with other foods, rancid fats destroy such essential food elements as vitamin A, carotene, vitamin D, vitamin E, pantothenic acid, pyridoxine, biotin, ascorbic acid and linoleic acid. An extreme instance of the vitamin deficiency induced by rancid fat has been reported by Fitzhugh and his associates² of the Food and Drug Administration, Washington, D. C.

Certain unexplainable abnormalities developed in control rats maintained for long periods on their routine

laboratory diets. Fitzhugh placed 20 pairs of albino rats, 21 days of age and equally divided between the sexes, on mixed diets consisting of 18 parts of casein, 60 parts of corn starch, 5 parts of brewers' yeast, 5 parts of whole dried liver, 4 parts of salt mixture, 2 parts of cod liver oil and either 6 parts of corn oil or 6 parts of lard which had been previously stored for several months at 35 F. The two dietary mixtures were prepared in sufficient quantities to last approximately six weeks and the mixtures stored in covered tin buckets at 35 F. The rancidity of the lard was established by organoleptic tests and the peroxide number determined. This was usually 41 millimols per kilogram as contrasted with 2 millimols per kilogram in fresh lard from the same batch.

During the rapid growth period of the first three months only a slight difference was apparent in the growth rates of the rats on the corn oil and rancid fat diets. Symptoms were noted in the rancid lard group after the animals had been on this diet for about a year. Control animals on the corn oil mixture were not affected. By the end of a year the rats fed the rancid lard were emaciated; with a typical humped back and roughened coat and a rapidly progressive weakness and paralysis, usually beginning in the hind legs. The emaciation, deformity and paralysis became extreme before death.

The characteristic necropsy findings were widespread focal degenerations of the skeletal muscles. Individual muscle fibers showed varying degrees of vacuolation with gray or tan pigmentation. An occasional pigmented microphage was noted within the muscle fibers. There was also a general visceral atrophy, particularly in the uterus. This was usually small and deeply pigmented. In the male testicular atrophy occurred. Since these results are similar to the "nutritional myodegeneration" described by previous investigators³ as characteristic of lethal vitamin E deficiency, Fitzhugh concluded that under his test conditions the main toxic effect of rancid lard was due to a complete destruction of vitamin E in his stored food mixtures. Confirming this conclusion, he found that nonrancid samples of the same batch of lard were nontoxic and nutritionally equivalent to the corn oil used in his control feedings. This is in agreement with data previously reported from the U. S. Department of Agriculture.⁴

As a practical application of these results the Washington investigators emphasize that dietary mixtures should be prepared as frequently as possible and if storage is necessary it should be at a subfreezing temperature. They found that the development of rancidity is more rapid in food mixtures than in unmixed lard and that little or no rancidity develops at 20 F.

Current Comment

CHICAGO VENEREAL DISEASE CONTROL PROGRAM

A program of venereal disease control in Chicago was begun in January 1937 by the Chicago Board of Health in cooperation with the United States Public Health Service, the Federal Works Agency and the Illinois Department of Public Health. The annual report¹ for 1942-1943, has now been published. The organization of the project centers in an office of venereal control, under which are six principal subdivisions dealing respectively with clinics, the Chicago Intensive Treatment Center, education, investigation, registry and statistics, including reporting and records. The program is staffed by a venereal disease control officer, who is a surgeon in the U. S. Public Health Service, two reserve public health officers and six other division heads. The objectives of the program, as stated at its inception Jan. 2, 1937, are (a) to uncover all possible cases of venereal disease, (b) to place each newly discovered case under competent medical care, (c) to keep infectious cases under treatment until they are no longer a menace to society or to themselves and (d) to prevent new infections by all possible means, including medical, educational and legal measures. The clinic section, oldest unit of the program, is designated as the diagnostic keystone of the entire project. More than 15,000 new cases of venereal disease were diagnosed through the year. Extensive case finding and case holding methods placed and kept large numbers of spreaders of venereal disease in the Chicago Intensive Treatment Center. The educational campaign enlisted tavern owners, and those signifying their willingness to cooperate were given certificates. A Central Register was maintained of all cases of venereal disease reported to the Chicago Health Department. A register is also kept of all physicians reporting such cases. The Central Register Section received an average of 10,000 items of information per month, of which approximately 38 per cent were laboratory reports of positive serologic reactions, 27 per cent morbidity reports and 29 per cent activity reports and case dispositions, the remainder being miscellaneous items. In the Clinic Section a central clinic and eight branch clinics were operated. Over 8,600 new cases of syphilis and 8,100 cases of gonorrhea, plus 514 new cases of other venereal diseases were treated in the Clinic Section. This represented a reduction of 16 per cent in syphilis cases under treatment as compared with the end of the previous year. A social service unit operated in connection with the clinic section and was reorganized during the year to form a follow-up service. The Chicago Intensive Treatment Center, formerly the Wesley Memorial Hospital, admitted its first patients on Oct. 29, 1942. Patients stayed an average of 10.9 days in this center; 2,189 patients were admitted during the year. The report also includes extensive tabulations of venereal disease reports in the city of Chicago and an analysis of control activities.

1. Progress Report Chicago Venereal Disease Control Program 1942-1943. Board of Health, Chicago 10.

THE RELATIONSHIP OF FLUORESCENT PORPHYRINS TO CANCER

Figge and his co-workers¹ found that in a large number of vertebrates the harderian or accessory lacrimal glands excrete porphyrins, giving a red fluorescence only in the animals most susceptible to experimental cancer, namely mice, rats and hamsters. They also found that in strains of mice highly susceptible to breast cancer the harderian glands were more fluorescent than in strains of low susceptibility. These observations suggested the hypothesis that "there is a direct or indirect relationship between porphyrin metabolism and the factors that determine cancer susceptibility." Naturally, the question arose whether porphyrins accumulate in places where human cancer frequently occurs, as, for instance, in the female genital tract. Jones and his associates² identified porphyrins spectroscopically in red fluorescent material in various parts of the tract in about one third of the cases examined, but the occurrence of such material was not related to any definite diseases. Probably these porphyrins originate mostly from decomposition of blood. The articles cited do not claim that porphyrins are directly carcinogenic, but a good basis has been developed for further and promising studies on their relationship to carcinogenesis and other processes.

MOTIVATIONS FOR TREASON

In a lecture given before the British Psychological Society on July 1, Major A. M. Meerloo¹ of the Netherlands, a psychiatrist, whose views are presumably based on personal experience during the German occupation of his country, asks why we are so deeply affected by the idea of treachery. The traitor, he says, will not admit his treachery, but, in his own mind, his conduct is justifiable. The traitors whom he saw in his own practice were not "wicked" but were weak characters: they had been disappointed in life, they were frustrated and had transferred their feelings to political phantoms. Some were affected by serious psychiatric abnormalities; some had homosexual tendencies and had been unable to find any real basis for living. Two who took a violent part in the betrayal of Holland had a strong mother fixation, which was projected on their country. Meerloo believes these people had a grievance and desired revenge on society for real or fancied ill treatment. The desire for revenge, he points out, is the outward impulse of an inner incapacity or weakness. It is the religion of the dissatisfied and the frustrated. For the psychologist, Meerloo states, the traitor is one who needs to break away from his environment or to do violence to it and his reasons for doing so are connected with his development, particularly during adolescence.

MEDICINE AND THE WAR

ARMY

TWENTIETH GENERAL HOSPITAL UNIT WINS HIGH PRAISE

Admiral Lord Louis Mountbatten, supreme allied commander in southeast Asia, recently presented a plaque to the 20th General Hospital, U. S. Army, in appreciation of treatment he received while suffering from an injury to his eye. Admiral Mountbatten became a patient at the army hospital after his left eyeball was cut by a branch which struck him while he was driving through the jungle on the Ledo front in Burma. During his week at the hospital in Assam Province, India, he was treated by Major Harold G. Scheie, who is credited with saving the sight of the injured eye. The plaque presented to the hospital unit has on its face a decorative design encircled by a border on which are the words "Supreme Allied Commander South East Asia." On the reverse of the plaque are the words "Presented to the 20th General Hospital, U. S. A. (Staffed by Volunteers from the University of Pennsylvania Under the Command of Colonel I. S. Ravdin), by Admiral the Lord Louis Mountbatten, G.C.V.O., C.B., D.S.O., A.D.C., Supreme Allied Commander of the Allied Forces in the South-East Asia Theatre, in Grateful Appreciation of the

Lord Mountbatten's gift: drawing of a plaque presented by the grateful British commander to the members of the 20th General Hospital, U. S. Army, who helped save his eye after a jungle accident.

Excellent Treatment He Received During the Week He Spent in the Hospital from an Injury to His Left Eye on the Ledo Front in Burma."

Appreciation of the treatment he received was also expressed by Lord Mountbatten in a letter to Colonel Ravdin, commanding officer of the hospital unit, who is on leave of absence from the Harrison professorship of surgery and the directorship of the Harrison Department of Surgical Research while serving with the army. Lord Mountbatten wrote "I am writing to thank you personally, and through you all members of the 20th U. S. General Hospital staff concerned, for the way I was looked after during my week in the hospital 7th to 14th March 1944 after receiving an injured eye. Throughout my stay I was treated with unbounded kindness and untiring attention. You can certainly be proud of the wonderful team that the University of Pennsylvania has committed to your care. If anything could increase my affection and regard for our American allies, my week with you would undoubtedly do so."

In addition, the unit has also received a captured Japanese battle flag autographed by Brig. Gen. F. D. Merrill and bears the notation "For 20th Gen. Hospital from 5307 with our thanks. Captured from Jap 18 Division near Kamaing, Burma, April 1944." In a letter to the commanding officer of the hospital

unit, General Merrill paid the following tribute to the unit: "On leaving this area for another assignment I wish to express to you and all members of your staff my very sincere appreciation of the efficient medical and surgical service which you have given. I understand fully that we have added a great amount of work to an already overworked staff, but it has always been comforting to know that when my sick and wounded reached your hospital they were assured of the very best medical and surgical treatment available in this theater."

The hospital unit also received letters of commendation from Major Gen. W. E. R. Covell and Brig. Gen. Lewis A. Pick in the China-Burma-India theater.

The 20th General Hospital Unit, organized by the University of Pennsylvania, was called into active service in May 1942. It includes physicians, surgeons, dentists, nurses, technicians, Red Cross workers and enlisted personnel. The unit has been in India since early last year and is the largest American army hospital in the China-Burma-India theater.

MALARIA CONTROL IN PACIFIC PROVES SUCCESSFUL

Brig. Gen. R. W. Bliss, Assistant Surgeon General of the Army, and Brig. Gen. F. W. Rankin, director of the Surgical Consultant Division, Office of the Surgeon General, who recently returned from an inspection tour of the Pacific area, state that the malaria control activities of the Army's Medical Corps have resulted in cleaning up the South Pacific of mosquito infestation. They visited Honolulu, Maui, Canton, Mandi (Fiji Islands), Tantonio, Noumea, Espiritu Santo, Guadalcanal, Russell Island, Tarawa, Makin, Kwajalein, Saipan, Tinian and Guam. Both officers were favorably impressed with the success of the malaria control work on all these islands.

General Bliss reported on the use of a new deodorant, PDB, which has supplanted the use of crude oil to kill flies and maggots in latrines. Where 5 gallons of oil daily had been used with only limited success, half a pound of PDB powder is now sprinkled twice a week for effective deodorization. Besides the added effectiveness of the deodorant, it saves much valuable transportation, space and manpower.

AMBULANCE PRESENTED TO ARMY MEDICAL DEPARTMENT

An army ambulance was recently donated to the Medical Department of the Army by the Thomasville, N. C., Society of the National Society, Children of the American Revolution. Lieut. Col. Mason Ladd, director of the legal division of the Office of the Surgeon General, accepted the gift on behalf of the War Department.

CAPTAIN WOODROW L. PICKHARDT A PRISONER OF WAR

Capt. Woodrow L. Pickhardt, formerly of Lawton, Okla., who was reported missing in action June 7, has recently been reported to be a prisoner of war of the German government. Dr. Pickhardt is a graduate of the University of Oklahoma School of Medicine, Oklahoma City, in 1937. He entered the service Aug. 11, 1942.

TREATMENT OF GONORRHEA

In the Technical Bulletin of Medicine, No. 96, recently issued by the War Department, penicillin is stated to be the drug of choice in the treatment of gonorrhea. The use of sulfonamides will be limited to cases not responding to adequate penicillin therapy and instances in which penicillin is not available through normal supply channels.

NAME GENERAL HOSPITAL FOR DENTAL CORPS OFFICER

The War Department recently announced the naming of the Rodriguez General Hospital at San Juan, Puerto Rico, in honor of the memory of Major Fernando E. Rodriguez, U. S. Army Dental Corps. Major Rodriguez, who died in 1932, was one of dentistry's foremost research scientists, pioneering in the study of the bacteriologic aspects of dental diseases. The results of his work were so fundamental that it has been used as the basis for all further scientific research along this line. He developed new techniques and methods of analysis and made many other contributions to the science of bacteriology. Major Rodriguez received a B.S. degree from Georgetown University, Washington, D. C., in 1924, after having served in the Army since 1917. He was a member of the District of Columbia Dental Society, a member of the International Association of Dental Research and a fellow of the American College of Dentists.

ARMY AWARDS AND COMMENDATIONS

Captain H. Myles Johnson

Capt. H. Myles Johnson, formerly of Fort Supply, Okla., and now attached to the famous Seagrave Hospital Unit headed by Lieut. Col. Gordon S. Seagrave, recently received a special citation from Brig. W. L. Boatner. The Seagrave Hospital Unit is with General Stilwell's forces, who are clearing northern Burma so that American engineers can extend the Ledo road to the Burma road. Dr. Johnson is credited with helping to save the lives of 2,000 Chinese soldiers on the battlefields. He has been in China, Burma, India theater of war for more than two years. Soon after the Myitkyina Airfield was captured by American and Chinese troops, the Seagrave Unit moved in. The citation reads "During this period he was under constant enemy fire, making his way over the most difficult of jungle terrain and, with utter disregard for personal safety, administered to the medical needs of both Chinese and American patients. The splendid performance of duty and disregard for personal safety reflects credit on his organization and the esprit de corps of the United States Army." Dr. Johnson graduated from the University of Oklahoma School of Medicine, Oklahoma City, in 1934 and entered the service Sept. 15, 1941.

Major George L. Thorpe

Major George L. Thorpe, formerly of Valley Center, Kan., and now a flight surgeon of a Liberator bomber group operating from an advanced air base in Italy, has been awarded the Soldier's Medal. He was decorated for the courage he displayed last February in rescuing an injured navigator from a burning plane that crashed near its home base. Unmindful of the intense heat and exploding ammunition, Dr. Thorpe rushed into the wreckage, hacking his way through burning debris to rescue a fellow officer, whom he succeeded in carrying out from what would have been a funeral pyre. Seconds later the burning ship exploded with a terrific impact, but the doctor and his charge were already safe. Dr. Thorpe graduated from Tulane University of Louisiana School of Medicine, New Orleans, in 1938 and entered the service Aug. 13, 1942.

Major Carl D. Makart

Major Carl D. Makart was recently awarded the Silver Star for gallantry in action. As soon as enemy bombs had set fire to an ammunition dump at Humboldt Bay, Dutch New Guinea, Dr. Makart, a regimental surgeon in the medical corps of the Fighting Forty-First Infantry Division, established an aid station near the scene and worked throughout the night until the following afternoon taking care of the casualties. While performing his duties Dr. Makart was in constant danger of being hit himself by shrapnel from flying bombs. Formerly of Chicago, Dr. Makart graduated from Creighton University School of Medicine, Omaha, in 1938. He was commissioned in the service Sept. 9, 1941 and was promoted to captain on Feb. 28, 1942 and to rank of major on Jan. 24, 1943.

Colonel Otis O. Benson Jr.

The Legion of Merit was awarded by the War Department to Col. Otis O. Benson Jr., formerly of Tower, Minn. The citation accompanying the award read "In his capacity as chief of Aero Medical Research at Wright Field from Sept. 6, 1940 to July 15, 1943 he was responsible for successfully developing, testing and standardizing all items of medical equipment used in connection with military aviation. His professional skill and organizing ability made it possible for his unit, during a period of rapidly changing requirements, to succeed in applying previously known principles of aviation medicine to the practical situations of modern warfare and solving new problems arising from unexpected developments in aerial combat." Dr. Benson graduated from Rush Medical College, Chicago, in 1930 and entered the service July 31, 1931.

Captain Amos V. Persing Jr.

The Bronze Star was recently awarded to Capt. Amos V. Persing Jr., formerly of Watsontown, Pa., for heroic achievement in action during the period Nov. 21, 1943 to Jan. 9, 1944 in Italy. He led his battalion medical section often under enemy artillery fire in treatment of wounded personnel. During a ten day period 500 rounds of artillery shells burst within the battalion area. This action took place at Cassino. Dr. Persing on this and other occasions in which casualties were heavy calmly and with great efficiency carried on his treatment of the wounded. Dr. Persing's action under fire reflects great credit on himself and the military service. Dr. Persing graduated from the University of Cincinnati College of Medicine in 1929 and entered the service Aug. 13 1942.

Captain Louis J. Feves

The Soldier's Medal was recently awarded to Capt. Louis J. Feves, formerly of Pendleton, Ore. The citation accompanying the award reads "for heroism displayed in the Gilbert Islands on Jan. 21, 1944. With complete disregard for his own safety he aided in the rescue of injured and recovery of deceased crew members of an airplane that had crashed on a heavily mined reef. This act of heroism reflected great credit on himself and the military service." Dr. Feves graduated from the University of Oregon Medical School, Portland, in 1935 and entered the service July 9, 1942.

Colonel Frederick J. Frese

Col. Frederick J. Frese, formerly of Yonkers, N. Y., was recently awarded the Legion of Merit for "exceptionally meritorious conduct in the performance of outstanding services in the South Pacific Area from Sept. 27, 1942 to June 1, 1944." Dr. Frese graduated from St. Louis University School of Medicine in 1938 and entered the service on completion of his internship in 1939.

Captain George H. Lage

A Presidential Citation has been issued to the parachute infantry unit to which Capt. George H. Lage, formerly of Portland, Ore., was attached as surgeon, for their work in spearheading the invasion of France and the taking of Carentan. Dr. Lage graduated from the University of Oregon Medical School, Portland, in 1939 and entered the service Sept. 22, 1942.

Captain Edward J. Doherty

Capt. Edward J. Doherty, formerly of Woodhaven, N. Y., was recently awarded the Silver Star and the Purple Heart for a leg wound which he sustained at Cherbourg. Dr. Doherty graduated from New York Medical College, Flower and Fifth Avenue Hospitals, New York, in 1934. He entered the service Aug. 7, 1942 and was sent to England in February 1944.

Colonel Walter S. Jensen

Col. Walter S. Jensen was recently awarded the Legion of Merit for "exceptionally meritorious conduct in the performance of outstanding services from July 31, 1941 until Oct. 5, 1942." Dr. Jensen graduated from the College of Medical Evangelists, Loma Linda, Calif., in 1924, and entered the service Oct. 22, 1925.

ORGANIZATION SECTION

Washington Letter

(From a Special Correspondent)

Oct. 23 1944.

Federal-State Program of Vocational Rehabilitation

Details of the expanded vocational rehabilitation program under the Federal Security Agency, recently initiated by Congress in amendments to the Vocational Rehabilitation Act (Public Law 113, 78th Congress) were outlined for THE JOURNAL today. They provide for federal aid to enable state boards of vocational education and state agencies for the blind to furnish disabled persons with all services necessary to render them employable or more advantageously employable. These services include medical and surgical care, hospitalization, physical and occupational therapy, prosthetic appliances, vocational counseling and training, maintenance during training, occupational tools and equipment, placement in employment and other necessary services.

Mentally as well as physically disabled persons are now eligible for rehabilitation. Except for certain groups of war disabled civilians and federal employees injured in line of duty, persons receiving physical restoration services or maintenance grants must be in financial need. (It was emphasized that rehabilitation of veterans with service connected disabilities is conducted through the separate program under the U. S. Veterans Administration.)

The Federal Office of Vocational Rehabilitation is responsible for establishing standards in the various areas of services, for technical assistance to the states and for certification of funds on the approval of state plans for vocational rehabilitation meeting the requirements of the authorizing act of Congress. On request, the Surgeon General of the U. S. Public Health Service has assigned Senior Surgeon (R) Dean A. Clark as chief medical officer and three other medical officers to assist in the organization of the physical restoration activities. A national professional advisory committee composed of representatives of fields of medicine actively concerned with rehabilitation, hospital administration, public health nursing, medical social work, physical therapy and occupational therapy has been appointed by the federal security administrator to assist the Office of Vocational Rehabilitation in the technical phases of physical restoration service.

State agencies have been advised of policies to be followed in organizing the physical restoration phases, and similar professional advisory committees are being appointed by all state rehabilitation agencies to guide them in establishing and maintaining professional standards for physical restoration.

Medical diagnosis and treatment of disabled persons under care of state rehabilitation agencies is limited to physicians licensed to practice medicine and surgery and otherwise qualified by training and experience to perform the specific services required. Criteria for the designation of medical specialists may include certification by the appropriate American medical specialty boards, fulfillment of the training and experience requirements for admission to examination by such boards, state agency standards for the qualification of physicians in particular specialties or approval of individual specialists by the state professional advisory committee. Rates of remuneration for physicians, nurses, dentists, physical therapists and other medical personnel for services in physical restoration are being established by state agencies in consultation with their professional advisory committees and will be similar to rates paid for similar work under state supervision, such as crippled children or workmen's compensation, or under federal supervision, such as that of the Veterans Administration or the U. S. Employees Compensation Commission. State rehabilitation agencies must purchase hospital care at inclusive rates. In approving state standards for hospital facilities the Office of Vocational Rehabilitation will for the present be guided by the list of hospitals approved by the American College of Surgeons. Preference will be given to hospitals having more than 100 beds with well developed specialty services, medical social service, physical

therapy and occupational therapy, in view of special requirements. Eligible to receive the service are any person in the United States, District of Columbia, Puerto Rico and Hawaii who has a disability that is (1) a substantial employment handicap, (2) static or (3) remediable to a substantial extent in a reasonable time. Said a spokesman "Vocational rehabilitation is designed to conserve the working usefulness of the civilian disabled. In restoring a disabled person to productive work he is being transferred from the public assistance rolls to the payrolls of industry, by which he resumes his status as a self-supporting member of the community."

Medical Economic Abstracts

Progress of Medical Service Plans

To form a basis for mutual comparison, the various medical society prepayment plans were asked by the Bureau of Medical Economics for as recent a financial report as it was possible to give. Some of the principal items of the reports received are given here. Copies of these reports in full are available for administrators of all existing and proposed plans.

Surgical Care, Inc.—This was organized late in 1942 to serve Jackson County, Mo., and Wyandotte County, Kan. Its contracts covered surgery, obstetrics, anesthesia and x-ray. On Jan. 31, 1944 it had a membership of 3,525 males and 5,144 females, including subscribers and dependents. Its income from subscribers up to Jan. 31, 1944 was \$23,448, of which it expended \$18,323.96 and now has a surplus of \$5,124.04.

Medical Expense Fund of New York, Inc.—According to recent advices (THE JOURNAL, May 27, p. 296) the Medical Society of the State of New York has unanimously endorsed the merger of the Community Medical Care, Inc., a medical insurance affiliate of the Associated Hospital Service, which has 43,000 subscribers, and the Medical Expense Fund of New York, Inc., with 1,200 subscribers. The new group will be known as United Medical Services.

Medical Service Association of Pennsylvania.—This was organized in June 1940 and serves the state of Pennsylvania. It offers only surgical contracts, and as of Dec. 31, 1943 it had 3,086 subscribers and 5,631 dependents, making a total of 8,717 entitled to service. Its income to the date given was \$45,722.02 and expenditures \$45,796.57, showing a loss of \$74.55 on operation. It had on hand a reserve of \$25,631.72.

Society Proceedings

COMING MEETINGS

- American Academy of Pediatrics, St. Louis, Nov. 9-11. Dr. Clifford G. Grullee, 636 Church St., Evanston, Ill., Secretary.
- American Society for the Hard of Hearing, New York, Nov. 10-12. Mr. Raymond H. Greenman, 1537 Thirty-Fifth St., N.W., Washington 7, D. C., Managing Director.
- Annual Conference of State Secretaries and Editors, Chicago, Nov. 17-18. Dr. Olin West, 535 N. Dearborn St., Chicago, Secretary.
- Association of Military Surgeons of the United States, New York, Nov. 2-4. Col. James M. Phalen, Army Medical Museum, Washington 25, D. C., Secretary.
- Central Neuropsychiatric Association, Chicago, October 31. Dr. Ernest M. Hammes, 1124 Lowry Medical Arts Bldg., St. Paul 2, Minn., President.
- Central Society for Clinical Research, Chicago, Nov. 3-4. Dr. Carl V. Moore, 602 S. Euclid Ave., St. Louis 10, Secretary.
- Midwestern Section of American Federation for Clinical Research, Chicago, Nov. 2. Dr. Richard H. Lyons, University Hospital, Ann Arbor, Mich., Secretary.
- New York State Association of Public Health Laboratories, Albany, Nov. 17. Miss Mary B. Kirkbride, New Scotland Ave., Albany 1, Secretary.
- Puerto Rico, Medical Association of, Santurce, Dec. 15-17. Dr. E. Martinez-Rivera, P. O. Box 3866, Santurce, Secretary.
- Southern Medical Association, St. Louis, Mo., Nov. 13-16. Mr. C. P. Loranz, Empire Building, Birmingham 3, Ala., Secretary.
- Western Surgical Association, Chicago, Dec. 1-2. Dr. Arthur R. Metz, 250 East Superior St., Chicago, Secretary.

Pittsburgh

Special Society Elections.—Dr. John D. Sturgeon Jr., Uniontown, is president of the Pittsburgh Pediatric Society, Dr. Joseph S. Baird vice president and Dr. Christian J. Stoecklein secretary-treasurer.—Dr. Kenneth E. Appel, Philadelphia, was chosen president-elect of the Pennsylvania Psychiatric Society at its sixth annual dinner meeting at the University Club, September 21, and Dr. George W. Smeltz was installed as president. Dr. LeRoy M. A. Maeder, Philadelphia, is secretary and Dr. Ralph L. Hill, Wernersville, the immediate past president. Speakers at the meeting included Comdr. James M. Henninger (MC) on "Navy Psychiatry, with Particular Reference to the South Pacific" and Lieut. Col. Baldwin L. Keyes, M. C., "Psychiatry in the Middle East."

TENNESSEE

Dr. Diggs Goes to Cleveland-Clinic.—Dr. Lemuel W. Diggs, since 1938 associate professor of medicine at the University of Tennessee College of Medicine, Memphis, has accepted an appointment as clinical pathologist in charge of the clinical laboratories of the Cleveland Clinic, Cleveland, effective January 1. Dr. Diggs graduated at Johns Hopkins University School of Medicine, Baltimore, in 1926 and was for three years a member of the department of medicine at the University of Rochester School of Medicine and Dentistry, Rochester, N. Y. He has been directing his attention to sickle cell anemia.

GENERAL

Anesthesia Session Planned.—Investigators wishing to present material for clinical research before the Eastern section of the American Federation for Clinical Research at a meeting in Boston, December 9, are urged to communicate with Dr. Orville T. Bailey, Harvard Medical School, 25 Shattuck Street, Boston, before November 15. An abstract of not over two hundred words should be submitted.

Louis Dublin Serves as Temporary Head of Red Cross.—Louis I. Dublin, Ph.D., New York, second vice president and statistician of the Metropolitan Life Insurance Company, on October 2 became temporary executive officer of the American Red Cross and will serve in this capacity until the return of Basil O'Connor, who is now on an inspection tour of Red Cross operations in France and Great Britain. Dr. Dublin is on loan to the Red Cross for a limited period. His normal assignment is as assistant to Mr. O'Connor, acting as coordinator of the various operating divisions of the Red Cross. In his new appointment Dr. Dublin will devote full time to Red Cross activities.

Annual Forum on Allergy.—The seventh annual Forum on Allergy will be held in the Hotel William Penn, Pittsburgh, January 20-21. A feature of the meeting will be the first award of the Marcelle Prize, established by the Marcelle Cosmetics, Inc., Chicago, in 1944 to be awarded to the author of the best paper on allergy appearing in the American medical literature during the year. The first prize will be for \$350 and the second for \$150. Physicians attending the session will have access to twelve study groups in addition to special lectures, motion pictures, demonstrations, symposiums and panel discussions. On Friday evening preceding the forum the American Association of Allergists for Mycological Investigation will hold its annual meeting, at which time the results of its cooperative research on allergy to fungi will be reviewed.

Meeting of Anesthetists.—The American Society of Anesthetists will meet in the Rice Hotel, Houston, November 2, and at the University of Texas Medical Branch, Galveston, November 3, as guests of the Texas Association of Medical Anesthetists. In addition to clinical demonstrations and round table discussions the following will speak:

Dr. Robert L. Sanders, Memphis, Tenn., Surgeon-Anesthetist Relationship.
Dr. Hubert R. Hathaway, San Francisco, The Postoperative Ambulatory Patient.
Lieut. Col. William J. Winter, M. C., and Comdr. Jarvis C. Youngblood (MC), War Anesthesia.
Dr. Ralph M. Waters, Madison, Wis., Imperfections of Inhalation Anesthesia.

At the dinner meeting Thursday evening speakers will include Dr. Ernst W. Berner, Houston, on "Anesthesia in the Development of Surgery" and Chauncey D. Leake, Ph.D., Galveston, "The Centennial of Anesthesia."

Award in Mental Hygiene Created.—The Albert and Mary Lasker Foundation, Inc., has established the Lasker Award of \$1,000 to be given annually through the National Committee for Mental Hygiene for outstanding service in the

field of mental hygiene. The new award will be conferred at the annual meeting of the committee in the autumn of each year. The purpose of the award is to recognize significant contributions to promoting mental hygiene and to making the broad field and program of mental hygiene more familiar to the general public. Each year the award will be made for a contribution in some special aspect of the field of mental hygiene which seems to be of most immediate and current significance. The recipient of the award will be selected by an anonymous jury chosen annually for its competence to judge accomplishment in a particular field. The award this year will be for mental hygiene work related to the war. The recipient will be chosen from among leaders who have done work in the general enhancement of the mental health of the men and women of the services, both while in service and during the period of rehabilitation, so far as developed at the time. The work must either have been completed or have been tested and won general acceptance within the year preceding the granting of the award. Recipients will not necessarily be limited to persons in the United States. If some outstanding contribution has been made abroad in a particular field, the award will be made jointly with the leading mental hygiene organization of that foreign country.

Industrial Hygiene Foundation.—The ninth annual meeting of the Industrial Hygiene Foundation of America will be held at the Mellon Institute, Pittsburgh, November 15-16. The theme of the meeting will be "Postwar Industrial Health." Among the speakers will be:

Dr. Hallowell Davis, Boston, Protection of Workers Against Noise.
Dr. Leonard E. Himler, Ann Arbor, Mich., Practical Psychiatry in Industry.
George K. Hill, Ph.D., Salt Lake City, Effectiveness of Tall Stacks in Minimizing Air Pollution from Industrial Plants.
Lieut. Col. Theodore F. Hatch, S. C., Upper Limits of Tolerance to Heat and Humidity.
Francis R. Holden, Ph.D., and W. C. L. Hemeon, M. S., Pittsburgh, Findings from Foundation Surveys of War Plants.
Dr. George W. Wright, Saranac Lake, N. Y., Medical Aspects of Compensation for Partial Disability from Silicosis.
Theodore C. Waters, Baltimore, Legal Aspects of Compensation for Partial Disability from Silicosis.
Marshall Dawson, Washington, D. C., Second Injury Funds as Employment Aids to the Handicapped.
Vandiver Brown, New York, Legal Developments in 1944 Respecting Industrial Health.
Andrew Court, Detroit, The Economic Basis of Health.
William M. Gafaer, D.Sc., Washington, D. C., Sickness Indemnification.
Nathan Sinai, D.P.H., Ann Arbor, Mich., Medical Expense Indemnification.
Dr. Carl M. Peterson, Secretary, Council on Industrial Health, American Medical Association, Chicago, Recent Developments in Pre-placement Physical Examinations.
V. P. Ahearn, executive secretary, National Industrial Sand Association, Increasing Importance of Industrial Health in Industrial Relations.

One session on "Putting the Disabled Veteran Back to Work" will be presided over by Dr. Clarence D. Selby, medical consultant, General Motors Corporation, Detroit.

Academy of Pediatrics.—The American Academy of Pediatrics has designated its meeting at the Hotel Jefferson, St. Louis, November 9-11, as a "Wartime Conference on Child Health." One session will be devoted to the control of rheumatic fever with the following speakers: Drs. Alexander T. Martin, New York; Rene Wegria, New York; Alexis F. Hartmann, St. Louis; Ann G. Kuttner, Irvington, N. Y.; T. Duckett Jones and Benedict F. Massell, Boston; Col. Leonard G. Rowntree, M. C.; John George Fred Hiss, Syracuse; George M. Wheatley, New York; Betty Huse, Washington, D. C.; Paul F. Dwan, Minneapolis; Louise F. Galvin, Richmond, Va., and Clark H. Hall, Oklahoma City. Other speakers on the program will include:

Dr. Madge T. Macklin, London, Ont., Erythroblastosis Fetalis.
Dr. Gerardo Varela, Jacuba, Mexico, Bacterial Dysenteries.
Drs. Grover F. Powers and Paul L. Boisvert, New Haven, Conn., Age as a Factor in Streptococcoses.
Dr. Wallace E. Herrell, Rochester, Minn., Penicillin, Its Use in Pediatrics.
Dr. Leslie Nelles Silverthorne, Toronto, Whooping Cough.
Dr. Hattie E. Alexander, New York, Treatment of H. Influenzae Infections in Children.
Dr. John A. Toomey, Cleveland, The Neuropathies.
Ernest Carroll Faust, Ph.D., New Orleans, Arthropod Borne Diseases.

A special feature of the meeting will be a symposium on parenteral therapy conducted by Dr. Hartmann and Drs. Allen M. Butler, Boston; Luther Emmett Holt Jr., Baltimore, and Sam Z. Levine, New York.

College of Surgeons Expands Graduate Training Program.—The American College of Surgeons announces the appointment of Major Gen. Charles R. Reynolds, M. C., retired, former surgeon general of the U. S. Army, as consultant in graduate training in surgery and of Dr. George H. Miller, dean and professor and head of the department of medicine, American University of Beirut, Beirut, Lebanon, as

director of educational activities. The appointments are part of an expanded program of graduate training in surgery of the college. Both physicians will have offices at the Chicago headquarters of the college. The department of graduate training in surgery is under the direction of Dr. Malcolm T. MacEachern, Chicago, chairman of the administrative board of the college. It will be responsible to the committee on graduate training in surgery and to the board of regents. In addition to General Reynolds and Dr. Miller, the staff of the department will consist of Dr. Paul S. Ferguson, director of surveys, three assistants who conduct the surveys, and the field representatives conducting the regular hospital standardization surveys under the direction of Dr. Earl W. Williamson, assistant director of the college, who aid as required in the graduate training program. The latter is a development of the basic work of the college in stimulating the improvement of hospital service. General Reynolds is leaving his position as director of the Pennsylvania state bureau of tuberculosis control, Harrisburg, Pa., where he has been serving for the past four years, to accept the new appointment. He was commandant of the Army Field Service Medical School, Carlisle Barracks, Pa., from September 1923 to 1931 and surgeon general of the Army for a four year term beginning 1935.

Western Surgical Association.—The fifty-second annual meeting of the Western Surgical Association will be held at the Drake Hotel, Chicago, December 1-2. At the annual dinner Friday evening the president of the association, Dr. Willis D. Gatch, Indianapolis, will speak on the "Prospects of Our Association." Other speakers will be Dr. Herman L. Kretschmer, President, American Medical Association, Chicago, and Capt. E. Eric Larson (MC) on "The Medical Aspects of Our War in the Pacific." Among other speakers on the program will be:

- Dr. Francis E. Clough, San Bernardino, Calif., Madura Foot.
Dr. Neil J. MacLean, Winnipeg, Man., The Technique for Closure of the Ring of Postoperative Abdominal Hernia.
Dr. Jacob K. Berman, Indianapolis, Intercapulothoracic Disarticulation of the Arm.
Dr. Erwin R. Schmidt, Ralph M. Waters and Noel A. Gillespie, M.D., Deaths.
Dr. Use of Thionacil in the Treatment of
Dr. Martin G. Brumack, San Jose City, Thyroidectomy by the Off the Trachea Method.
Dr. Herbert H. Davis, Omaha, Amino Acids Used Intravenously in Surgical Patients.
Dr. Earl C. Padgett, Kansas City, Mo., and John H. Gaskins, Use of Skin Flaps in the Repair of Scarred or Ulcerative Defects over Bone and Tendons.
Dr. Louis P. Good, Texarkana, Texas, Origin and Growth of an Adenoma of the Islands of Langerhans.
Dr. Stanley R. Maxeiner and Col. Harry E. Bundy, M. C., Resection of Pancreas for Hyperinsulinism.
Dr. Warren H. Cole and John T. Reynolds, Chicago, Resection of the Duodenum and Head of the Pancreas for Carcinoma.
Dr. Thomas C. Orr, Kansas City, Pancreaticoduodenectomy for Carcinoma of the Ampulla.
Dr. J. Dewey Bisgard, Omaha, Gastric Resection for Certain Acute Perforated Lesions of the Stomach and Duodenum with Diffuse Soiling of the Peritoneal Cavity.
Dr. Stuart W. Harrington, Rochester, Minn., Surgical Treatment of Pharyngo (Esophageal) Diverticulum (Review of 140 Cases).
Dr. Robert L. Sanders, Memphis, Tenn., Review of One Hundred Subtotal Gastrectomies for Benign Ulcer.
Dr. Henry K. Ransom, Ann Arbor, Mich., Gastrojejunocolic Fistula.
Dr. Claude F. Dixon and Raymond E. Benson, Rochester, Surgical Management of Signoidal Carcinoma Involving the Urinary Bladder.
Dr. Owen H. Waagensteen, Minneapolis, Preservation of the Splinters and Intestinal Continuity in Operation for Carcinoma of the Rectal Ampulla.
Dr. Charles G. Johnston and Elisha S. Gurdjian, Detroit, Peripheral Nerve Injury in Association with Fractures of Long Bones.
Dr. Loyal Davis, George E. Perret and Walter W. Carroll, Chicago, Repair of Peripheral Nerves in the Presence of Extensive Soft Tissue and Bone Injuries of the Extremities.
Dr. Henry W. Meyerding, Rochester, Chronic Sclerosing Osteitis: Differential Diagnosis.
Dr. Kellogg Speed, Chicago, Treatment of Infected Pin Operations for Fractures of the Neck of the Femur.
Dr. Melvin S. Henderson, Rochester, Status of the Bone Graft in Ununited Fractures of the Neck of the Femur.
Dr. Glen Evan Cheley, Denver, Personal Evaluation of Vitallium Cup Arthroplasty of the Hip Joint.

Southern Medical Association.—The thirty-eighth annual meeting of the Southern Medical Association will be held at the Municipal Auditorium and the Jefferson Hotel, St. Louis, November 13-16, under the presidency of Dr. James A. Ryan, Covington, Ky., who assumed the position on the death, May 2, of Dr. William T. Wootton, Hot Springs National Park, Ark. The first general public session has been designated President's Night, at which Dr. Ryan will discuss "The Public's Obligation to the Medical Profession." Other speakers will include Dr. Herman L. Kretschmer, President, American Medical Association, Chicago, on "The Progress of Medicine During the Past Fifty Years," and Major Albert J. Stowe, G. S. C., "Be Vigilant and Mumi!" A feature of this meeting will be the presentation of the Leslie Dana Gold Medal by the St. Louis Society for the Blind to Miss Linda Neville,

Lexington, Ky. (THE JOURNAL, July 8, p. 730). A second public session Wednesday evening will be devoted to "Medicine in the War," at which the speakers will be Capt. Alphonse McMahon (MC), on "Civilian Tropical Disease Problems Following Demobilization"; Col. Howard A. Rusk, M. C., "New Horizons in Medicine," and Rear Admiral Luther Sheldon Jr. (MC), "Navy Medicine in the War." Among the many speakers on the program, which is further divided into general clinical and sectional sessions, are:

- Dr. William C. MacDonald, St. Louis, Thionacil in the Management of Hyperthyroidism.
Drs. Vincent de P. J. Derbes, Hugo T. Engelhardt and Theodore A. Watters, New Orleans, Management of Migraines.
Dr. George T. Harrell Jr., Dr. William L. Venning Jr. and William A. Wolff, Ph.D., Winston-Salem, N. C., Treatment of Rocky Mountain Spotted Fever.
Dr. John T. Howard, Baltimore, Experiences with the Gastroscope over a Period of Six Years.
Dr. Charles F. Mohr, Baltimore, Results of Penicillin Treatment in Neurosyphilis.
Capt. Arthur C. Allen, M. C., and Dr. Sophie Spitz, M. C., Pathology of Scrub Typhus (Tsutsugamushi Fever).
Drs. Walter S. Lawrence and Walter W. Robinson, Memphis, Radio-sensitive Parasellar Tumors: Case Reports.
Dr. Harry S. Bernton, Washington, D. C., Castor Bean Sensitiveness: Case Report.
Capt. Frederick A. Jostes (MC), Physical Medicine: Its Importance in Any Rehabilitation Program.
Col. John C. Burch, M. C., and Lieut. Col. Herbert C. Fisher, M. C., Appendicitis Mortality.
Dr. Robert A. Knight, Memphis, Treatment of Fractures of the Tibial Condyles.
Capt. Laman A. Gray, M. C., Treatment of Gonorrhea in the Female with Penicillin.
Dr. James A. Seaman, Springfield, Mass., Endocervicitis as a Factor in Urologic Infections.
Dr. Victor K. Allen, Tulsa, Okla., Perirectal Fistula as a Port of Entrance for Torula Encephalitis.
Dr. Murdoch S. Eyles, Atlanta, Ga., Magnetic Removal of Foreign Bodies from the Food and Air Passages Under Fluoroscopic Guidance.
Dr. Stuart C. Cullen, Iowa City, Use of Curare in Anesthesia.

Other features of the session will be a symposium on the essentials of medical education participated in by:

- Dr. Edwin P. Lehman, Charlottesville, Cultural Values in Medical Education.
Dr. Jacques P. Gray, Richmond, Va., Undergraduate Curriculum in Medicine.
Dr. Hiram W. Kostmayer, New Orleans, Medical Education Above the Undergraduate Level.
Dr. Cornelius O. Bailey, Los Angeles, Postwar Medical Education.
Dr. Victor Johnson, Secretary, Council on Medical Education and Hospitals, American Medical Association, Chicago, Postgraduate Training After the War.
Miss Marion A. Murphy, Librarian, Washington University School of Medicine Library, St. Louis, The Effects of the War on the Medical School Library.

During the meeting of the Southern Medical Association other groups holding sessions will be the southern branch of the American Public Health Association, the National Malaria Society, American Society of Tropical Medicine, American Academy of Tropical Medicine and the southern chapter of the American College of Chest Physicians. The thirtieth annual meeting and dinner for women physicians of the Southern Medical Association will be held November 15.

FOREIGN

Personal.—Dr. Alan N. Drury, director of the Lister Institute, London, has been named honorary secretary of the advisory board to the Beit Memorial Trustees, the group sponsoring the memorial fellowships for medical research.

Academy of Medical Sciences in Russia.—An Academy of Medical Sciences of the Union of Soviet Socialist Republics has been organized, the *British Medical Journal* reports. It is to be set up under the People's Commissar for Health and will have three departments: medical biology, hygiene, microbiology and epidemiology, and clinical medicine.

Deaths in Other Countries

Israel J. Kligler, Ph.D., formerly an associate of the Rockefeller Institute for Medical Research, died in Jerusalem, September 23. Dr. Kligler, who had held the Jacob Epstein chair of bacteriology and hygiene at Hebrew University since 1926, came to Palestine in 1943 as head of the malaria research unit sent by Hadassah the Zionist women's organization. Dr. Kligler, who was born in Austria in 1889, received his doctor of philosophy degree at Columbia University in 1915.

CORRECTION

Therapeutic Effect of Para-Aminobenzoic Acid in Louise Borne Typhus Fever.—In the paper by Yeomans et al. in THE JOURNAL, October 7, the authors request that the following correction be made in table 6 on page 354: The average age of the B group should be changed from 18 to 27.

LONDON

(From Our Regular Correspondent)

Sept. 30, 1944.

Chair of Child Health Established in London

With Lord Nuffield's approval the trustees of the Nuffield Foundation have allocated \$50,000 a year for ten years to provide a chair of child health in the University of London, an offer which has been gratefully accepted by the trustees of the university. This grant will enable a postgraduate institute of child health to be created for teaching and research on all aspects of child health. It is proposed that the institute shall be associated with the principal children's hospital in this country—the Hospital for Sick Children, Great Ormond Street, London, and with the obstetric department of the British Postgraduate Medical School at the Hammersmith Hospital. Lord Nuffield and the trustees of his foundation believe that the promotion of child health must have a prominent place in the organization of the future health services of the country. They appreciate that the development of research and training in this sphere requires new and enlarged facilities. They desire that the exceptional resources of the University of London for postgraduate education and research may be developed in a manner which will make the new Institute of Child Health worthy of the capital city of the empire.

The provision of academic centers for the teaching of child health has already been undertaken in several provincial universities, and the Nuffield Provincial Hospitals Trust has within the last three years made a substantial contribution to the University of Durham to assist in creating a chair of child health at King's College, Newcastle-on-Tyne. Edinburgh has had such a chair since 1931, and another has just been established at Liverpool by collaboration of the university with the city council. The title of the new chair is noteworthy. This country has never been backward in the study of pediatrics; on the contrary, it has made great advances in that subject. But "Hospital" or "Department for Diseases of Children" has always been the designation for the institution concerned. Now the idea has become popular that the medical profession has been too preoccupied with the treatment of disease, and that prevention, or the preservation of health, should have a more prominent place as an objective. Calling the government's projected scheme a "National Health Service" instead of a "National Medical Service" is a case in point.

The Doctor's View of the Proposed National Health Service

Under the caption "The Doctor's View," Lord Dawson, president of the British Medical Association, reviews the government's proposals for a national health service in a letter to the *Times*. The medical profession, he says, has realized that the growth of medical knowledge was outstripping the organization of medical practice and for nearly twenty-five years has put forward plans to improve the availability of its services. There is little dispute over objectives, then, but there are differences about methods. The profession insists on a substantial share in the planning and administration of the proposed service at every level, Lord Dawson states. The service should be guided by those persons, both medical and lay, who have expert knowledge. Do local authorities know anything about medicine? he asks. How can they plan and administer, unaided, hospital services? In the war we use expert guidance. Why attempt to do otherwise with medicine, which becomes more complex year by year?

We accept the proposal that this nationwide service, which spends public money, must be under theegis of a minister responsible to parliament, Lord Dawson says, but we claim also that, for the service to be efficient, the medical profession must have a responsible share in its planning and administration. To effect this at the center would be relatively easy if the two sides were like minded, but local administration has inherent difficulties, because its present shape and the proposed service would be misfits, it is claimed. Since the reconstruction of local government will be impossible amid pressing postwar problems and it is undesirable to delay laying the foundations of the service, it is acknowledged that we must seek a provisional, "make do" administration, provided skilled guidance is secured and provided the voluntary hospitals are ensured equality of opportunity and private practice is given full freedom. These requirements would be met if medical and other skilled persons were made partners with the elected representatives of the people on the local bodies. The profession seeks to share in, not to dominate, the work of planning and execution.

Experience has shown that advisory committees standing outside the executive body are futile, the letter continues. The inadequacy of local bodies, as now constituted, to administer highly technical services is well known. But extraneous forces obstruct satisfactory settlement. One political school desires to seize this opportunity for furthering its ideology, which would mean whole time employment for medical men as part of the civil service, paid by salary. The impact of this influence, in the face of the government's repeated assurance that it has no such intentions, undermines confidence, Lord Dawson points out. Regarding the voluntary hospitals, suggestions are being made to transfer the administration of all hospitals to a central board. These suggestions are unfortunate. It is most important to take advantage of the knowledge, interest and local patriotism of each area and put responsibility on it. Central control would take the heart out of local government and lead to inanimate uniformity. The smooth running of a coordinated hospital service for each area under university influence is the foundation of any comprehensive service, the president's letter concludes.

The Dalton Centenary

John Dalton, who founded modern chemistry by putting the atomic theory on a quantitative basis, worked in Manchester, where he taught mathematics and physics. He contemplated entering the medical profession, but the expense was too great. He had a defect of color vision, now known as "daltonism," which he turned to account by producing his theory on the subject. The centenary of his death has fallen this year. It is therefore fitting that a Manchester physician, Dr. E. M. Brockbank, who has made Dalton's life a study, has published a book entitled "John Dalton—Some Unpublished Letters of Personal and Scientific Interest with Additional Information about his Colour Vision and Atomic Theories." When the 1929 meeting of the British Medical Association was held at Manchester Dr. Brockbank, president of the Section of the History of Medicine, gave an address on "John Dalton—Experimental Physiologist and Would-Be Physician." He had access to Dalton's letters and other relics and has made a thorough study of the subject.

Research at Oxford and Cambridge by Chinese

Five Chinese professors have arrived in Britain and will be the guests of certain colleges of Oxford and Cambridge. Chang Tsu-King, professor of the history of science at the Central China University, will reside in Christ's College, Cambridge, to study that subject. Yin Hung-Chang, professor of plant biochemistry at the Associated Southwestern Universities (Tsing Hua), Kunning, will do research at St. John's College, Cam-

bridge. Fan Tsen-Chung, head of the foreign languages department at the National Central University, Shapingpa, will do research in English literature, with special reference to English knowledge of China, and reside at Balliol College, Oxford. Chang-Hui-Wen, head of the department of public administration and political science at the Central University of China, will study public administration at Corpus Christi College, Cambridge. R. C. Fang, head of the foreign languages department, Wuhan University, Kiating, will do research in English literature at Trinity College, Cambridge.

Buenos Aires

(From Our Regular Correspondent)

Sept. 15, 1944.

Quinine and Malaria

Quinine is available in Argentina in scanty amounts. It is sold to the public only for malaria therapy and when public health authorities approve its use for other purposes. The government recently appointed a committee, as a branch of the National Department of Public Health, for studying the possibilities of obtaining quinine substitutes. A fund of \$15,000 was awarded for the studies. Drs. Carlos A. Alvarado, head of the National Antimalarial Department, Prudencio Santillan, secretary of the department, Cecilio Romano, head of the Instituto de Medicina Regional of the University of Tucumán, and Horacio Descole, head of the Lillo Institute of Tucumán, are the main members of the committee. The preliminary essays gave promising results. Further botanic and pharmacologic researches are progressing.

The government recently awarded \$150,000 to the national department for expenses incurred in the antimalarial crusade in the central and northern regions of the country. Regulations for free distribution of antimalarial drugs and plans for the crusade were submitted to the government by Dr. Carlos A. Alvarado, head of the National Antimalarial Department, and were approved. A batch of 400 larvogenic fishes was recently sent to the National Antimalarial Department by the Rockefeller Institute.

Beta Vulgaris and Pollinosis

Drs. L. Herraiz-Ballester and J. V. Monticelli recently lectured before the Argentine Society of Biology. They said that the coastal variety of Beta vulgaris grows abundantly near Bahía Blanca in Buenos Aires. The plant produces large amounts of pollen between October and December up to the end of the second week of December. Its pollen is the most frequent causal agent of pollinosis in the region, as shown by the results of skin tests, which were done on 150 patients with pollinosis. The pollinosis section of Bahía Blanca is heavily loaded with the pollen of Beta vulgaris, which fulfils Thomsen's postulates. Pollinization of this chenopodiacea herb precedes or accompanies pollinization of gramineous plants. The fact is of importance, they said, especially in connection with therapy of the disease.

Brief Items

Pamphlets for education of the public on poliomyelitis are being distributed to the public by the government of Buenos Aires. The measures for preventing the disease are explained.

A celebration was held recently at the Faculty of Medicine of La Plata, which recently reached its twenty-fifth anniversary.

Drs. Armando Marotta and Nicanor Palacios Costa were recently appointed president and numeric member of the Academia Nacional de Medicina of Argentina. The library of the academy was officially opened on this occasion. It has more than 40,000 volumes.

Dr. Carlota Pereira de Queiroz of Rio de Janeiro recently delivered a lecture at the National Academy of Medicine of Buenos Aires. She spoke on the applications of hematologic examination to social medicine.

BELGIUM

(From Our Previous Correspondent)

Sept. 21, 1944.

Gratitude of the Belgians

The people of Belgium deeply appreciate the liberation of our country by the Allies. They have shown their patriotic enthusiasm for the cause of liberation and their admiration for your army. We, the Belgian physicians, wish to express also our deep gratitude to your country and our admiration for your army. We are now able to see for ourselves on our reconquered soil the amazing organization of war surgery that has been built up by the Allies at the front. Because of our experience with the hospitals during the war of 1914-1918 we can appreciate the progress achieved in the care of the wounded, and we propose to learn from contact with your medical officers the advances in war surgery that have given such good results in this war.

I wish to write a few words regarding our experiences during the occupation: The practice of all Belgian physicians was regulated by a dictatorial order which had many arbitrary rules (for authorization to practice, location of physicians and similar matters). Fortunately these regulations were received generally with inertia, and 90 per cent of physicians continued practicing without openly protesting against the regulations, suffering vexation, to be sure, but practically ignoring their existence.

As for the Belgian medical press, two journals continued to be published, one in Flemish and one in French. Some of the material of medical journals which were suppressed by the invaders was provisionally published by the International Office of Medico-Military publications in the *Archives médicales Belges* from May 10, 1940. We never could obtain any medical literature except from Germany. All papers were suppressed by the invaders. The literature that we received consisted of medical items from Swiss journals sent to us in envelopes as if they were letters.

The nightmare is over now. The medical profession and the rest of the country are ready to resume their normal place in the world.

Marriages

ROBERT PAYNE BECKWITH JR., Roanoke Rapids, N. C., to Lieut. Nancy Margaret Kimbrough of Romney, W. Va., August 8.

WILLIAM FRANCIS KILLY, Birmingham, Ala., to Miss Margaret Helene McMenamin at San Francisco, September 25.

ARNOLD W. BROCKMOLE, Evansville, Ind., to Miss Martha Frances Jakubak of St. Louis in Cleveland, September 9.

EUGENE LEONARD WATKINS, Worcester, Mass., to Miss Victoria Pauline Peake of Brooklyn, September 23.

EDWARD MORSE SHEPARD to Miss Elizabeth Wendell Yates, both of New York in Nantucket, Mass., September 5.

HUBERT J. THOMAS, Dallas, Texas, to Miss Joella Henderson of Burkett in Wichita Falls, July 12.

GEORGE F. McAULIFFE, North Vernon, Ind., to Miss Sally C. Edelen of Bardstown, Ky., April 15.

LAURENCE BRUGGERS, St. Anne, Ill., to Miss Edith Lois Fuller of Amesbury, Mass., July 31.

IRVING E. BENYENISTE, Los Angeles, to Miss Angela Gower Cole of Minot, N. D., August 6.

GEORGE PLATT PILLING IV, Philadelphia, to Miss Barbara Bosworth of Denver, October 2.

FREDERICK YATES to Mrs. Lou E. Cunningham, both of Washington, D. C., September 9.

EUGENE B. BRODY, Columbia, Mo., to Miss Marian Hohen of Evanston, Ill., recently.

RONNEY CHARLES TURNER, Norfolk, Va., to Miss Mary Anna Ayers, September 3.

LAWRENCE LIMBERT, Norristown, Pa., to Miss Lois Fisher of Harrisburg, July 5.

Deaths

Charles St. John Butler * Medical Director, Rear Admiral, U S Navy, retired, Bristol, Tenn., University of Virginia Department of Medicine, Charlottesville, 1897; entered the medical corps of the U S Navy as a lieutenant (jg) in 1900, advanced through the various grades to that of rear admiral in 1935, retired on April 1, 1939, instructor in bacteriology and tropical medicine intermittently at the U S Naval Medical School from 1907 to 1921 and commanding officer from 1921 to 1924 and from 1927 to 1932, formerly professor of tropical medicine at George Washington University School of Medicine, Washington, D C., and Hahnemann Medical College and Hospital, Philadelphia, commanding officer, U S Naval Hospital, Brooklyn, from 1932 to 1935, director general of public health of the republic of Haiti from 1924 to 1927, commanding officer of the U S Naval Medical Supply Depot in Brooklyn, 1935-1936 and the U S Naval Medical Center in Washington from 1936 to 1938, detached March 31, 1939 as president of the naval retiring board and board of medical examiners and naval retiring board for officers of the medical corps, specialist certified by the American Board of Internal Medicine, served as a member of the medical board of the National Research Council, the Subcommittee on Medical Research, the National Malaria Committee, the National Advisory Health Council, the scientific board of the Gorgas Memorial Institute of Tropical and Preventive Medicine, the American Association for the Advancement of Science, the Washington Academy of Sciences, the American Association of the History of Medicine, the American Society of Clinical Pathologists and the Association of Military Surgeons of the United States, member and past president of the American Academy of Tropical Medicine, New York Society of Tropical Medicine, American Society of Tropical Medicine, the Washington branch of the Society of American Bacteriologists and the Helminthological Society of Washington, honorary member of the Society of Medicine, Haiti, fellow of the American College of Surgeons, American College of Physicians and the New York Academy of Medicine, decorated with the medal of honor and merit of Haiti, received a letter of commendation from the U S Navy Department for service in World War I, awarded the LL.D. degree by the Emory and Henry College in 1932, author of "Syphilis Sive Morbus Humanus", died October 7, aged 69, of cerebral hemorrhage.

Edward Shearman McSweeney * New York, Bellevue Hospital Medical College, New York, 1898, member of the American Association for Thoracic Surgery, American Association of Industrial Physicians and Surgeons, American Trudeau Society and the National Tuberculosis Association, fellow of the American College of Physicians, specialist certified by the American Board of Internal Medicine, formerly demonstrator of anatomy and lecturer on tuberculosis treatment and convalescent care at the New York University Medical College, formerly medical superintendent of the Sea View Hospital in Castleton Corners, N Y., and the Tuberculosis Sanatorium of the New York City Department of Health in Otisville, N Y., served as medical director of the New York Telephone Company, for many years on the board of visitors of the New York State Hospital, Ray Brook; chairman of the medical board, Tuberculosis Preventorium for Children, Farmingdale, N Y., consulting physician to the Grasslands Hospital, Valhalla, N Y., Mary Immaculate Hospital, Jamaica, and St. John's Long Island City Hospital, Long Island City, served on the medical board of the Stony Wold Sanatorium, Lake Kashaqua, N Y., Workmen's Circle Sanatorium, Liberty, N Y., and the Sanatorium Gabriels in Gabriels, received the degree of doctor of public health from New York University in 1921, died September 17, aged 66, of coronary thrombosis.

William Bradley Breed * Boston, Harvard Medical School, Boston, 1920, associate in medicine at his alma mater, member of the committee on publications, councilor and chairman of the war participation committee of the Massachusetts Medical Society, member of the New England Heart Association and the American Clinical and Climatological Society, fellow, regent and president of the board of governors of the American College of Physicians, associate editor from 1923 to 1937 and on the editorial board from 1937 to 1942 of the *New England Journal of Medicine*, specialist certified by the American Board of Internal Medicine, member of the honorary staff, House of the Good Samaritan, since 1920 on the staff and at House of the Good Samaritan of the executive committee of the Massachusetts General Hospital died in the Phillips House of the Massachusetts General Hospital August 21, aged 51, of carcinoma.

Jeremiah T. Simonson * New York, New York Homeopathic Medical College and Hospital, New York 1891, emeritus professor of pediatrics at his alma mater, now known as the New York Medical College, Flower and Fifth Avenue Hospitals, past president of the American Institute of Homeopathy, member of the American Academy of Pediatrics, specialist certified by the American Board of Pediatrics Inc., in 1941 received the gold certificate from his alma mater awarded to alumni who are still in active practice fifty years after graduation, consultant on the staffs of the Fitch Memorial Hospital, Neptune, N J., Metropolitan Hospital and the Yonkers General Hospital, Yonkers, N Y., consulting pediatrician to the Flower and Fifth Avenue Hospitals, where he died September 30, aged 74 of hypernephroma of the right kidney and coronary sclerosis.

Joseph Marshall Flint, New Haven, Conn., Johns Hopkins University School of Medicine, Baltimore, 1900, for many years professor of principles and practice of surgery at the Yale University School of Medicine, at one time professor of anatomy at the University of California, San Francisco, fellow of the American College of Surgeons, served overseas during World War I commander of the Yale University Medical Unit and later commanding officer of Mobile Hospital number 39, named liaison officer, American Expeditionary Forces, when he left the service had been cited for conspicuous and meritorious service and was decorated by the French government, formerly chief surgeon at the New Haven Hospital and the New Haven Dispensary, died in Seal Harbor Maine September 16 aged 72 of coronary embolism.

Robert Law Cunningham * Los Angeles, Johns Hopkins University School of Medicine, Baltimore, 1907, clinical professor of medicine at the University of Southern California School of Medicine, specialist certified by the American Board of Internal Medicine, past president of the Clinical and Pathological Society, now the Los Angeles Academy of Medicine, Los Angeles Tuberculosis Association and the California Tuberculosis Association, fellow of the American College of Physicians, member of the American Trudeau Society and the National Tuberculosis Association, served on the staffs of the La Vina Sanatorium, La Vina, the Hospital of the Good Samaritan, Barlow Sanatorium and Children's and St. Vincent's hospitals, died September 10, aged 63 of coronary thrombosis.

Hugh Spencer McKeown * New York, Baylor University College of Medicine, Dallas, 1922, member of the American Academy of Ophthalmology and Otolaryngology, fellow of the American College of Surgeons, specialist certified by the American Board of Ophthalmology, served as assistant clinical professor of ophthalmology at the Columbia University College of Physicians and Surgeons, police surgeon at Bronxville and Westchester County, attending surgeon at the Institute of Ophthalmology of the Presbyterian Hospital, chief of the ophthalmologic service, Lawrence Hospital Bronxville on the staff of the Vanderbilt Clinic, died in the Harkness Pavilion, September 14, aged 49, of coronary thrombosis.

Charles Henry Tilghman Lowndes * Medical Director, Rear Admiral, U S Navy, retired, Durham, N C., University of Maryland School of Medicine, Baltimore, 1888, entered the medical corps of the U S Navy as an assistant surgeon on April 12, 1889, rose through the various grades to that of rear admiral in 1919, retired March 1, 1929 on own application after thirty years' service, formerly medical director of the Georgetown University Hospital, Washington, D C., author of "Reports on Results of Indian Conditions on Various Reservations", died in the Naval Hospital Bethesda Md., September 25, aged 78.

Edward Luther Whitney * Walla Walla Wash., Baltimore Medical College, 1895, served as president of the Walla Walla Valley Medical Society, specialist certified by the American Board of Internal Medicine, fellow of the American College of Physicians, formerly professor of physiologic chemistry at his alma mater and associate professor of physiologic chemistry, pharmacy and clinical pathology at the University of Maryland School of Medicine, member of the staffs of the Walla Walla General and St. Mary's hospitals, died September 13, aged 73, of bilateral hemiplegia.

Thomas Warren Allred * Nephi, Utah, Northwestern University Medical School, Chicago, 1923, served as county and city physician, president and for many years a member of the county board of education, died in the Payson City Hospital, Payson, August 6, aged 57.

Alexander Locke Anderson, Wolfville, N S., Canada, Long Island College Hospital, Brooklyn, 1898, practiced in Brooklyn for nearly forty years, died June 29, aged 70.

Louis Baer * Philadelphia, Medico-Chirurgical College of Philadelphia, 1913, specialist certified by the American Board of Otolaryngology, served an internship at the Garretson Hos-

pital; on the staff of the Mount Sinai Hospital; died in the Pennsylvania Hospital August 4, aged 56.

Frederick Clifton Ballard ♂ Rushford, N. Y.; University of Buffalo School of Medicine, 1898; for many years county coroner; for more than twenty years on the board of education of Rushford, serving at one time as president; health officer and school physician; on the staff of the Genesee Country Memorial Hospital, Fillmore; died August 16, aged 68, of cerebral hemorrhage and cirrhosis of the liver.

Robert Lenox Barnes ♂ Columbus, Ohio; Starling-Ohio Medical College, Columbus, 1910; associate of the American College of Physicians; member of the American Heart Association, American Society for the Study of Arthritis and the Columbus Academy of Medicine; on the attending staff, Mount Carmel Hospital; died August 2, aged 58, of cerebral hemorrhage.

Philip John Bartle, Eugene, Ore.; Barnes Medical College, St. Louis, 1896; member and past president of the Oregon State Medical Society; past president of the Lane County Medical Society; member of the Pacific Northwest Medical Association; served as president of the Oregon Association of Hospitals; for many years on the staff of the Eugene Hospital and Clinic; died September 5, aged 70, of ruptured aortic dissecting aneurysm.

John A. Biever, Mount Joy, Pa.; College of Physicians and Surgeons, Baltimore, 1885; died August 27, aged 86, of carcinoma of the liver.

William Henry Blanchette ♂ Fall River, Mass.; Baltimore Medical College, 1896; served during World War I; major, medical reserve corps, U. S. Army, not on active duty; died August 1, aged 71.

Braxton B. Blount, Punta Gorda, Fla.; Louisville Medical College, Louisville, Ky., 1890; examiner for the local Selective Service Board; died August 14, aged 79.

Walter William Brand ♂ Toledo, Ohio; Jefferson Medical College of Philadelphia, 1894; fellow of the American College of Surgeons; honorary president of the Ohio Obstetrical Society; formerly health officer of Toledo; for many years on the staff of St. Vincent's Hospital; resigned as chief of staff in 1934 and as director of obstetrics in 1942 at the Women's and Children's Hospital, where he died October 2, aged 73, of cerebral thrombosis.

Henry George Crease ♂ Bakersfield, Calif.; Jefferson Medical College, Philadelphia, 1891; formerly owner of the Trinity Hospital; died August 15, aged 78.

Annie Sturges Daniel ♂ New York; Woman's Medical College of the New York Infirmary for Women and Children, New York, 1879; for more than sixty years a member of the staff of the New York Infirmary for Women and Children; on the editorial board of the *Medical Woman's Journal*; author of "A Cautious Experiment"; died August 10, aged 85.

Cyril Ostello Dozer, Roseville, Ohio; Eclectic Medical College, Cincinnati, 1919; member of the Ohio State Medical Association; vice president of the school board; served during World War I; on the staff of the Bethesda Hospital, Zanesville; died in the Good Samaritan Hospital, Zanesville, August 21, aged 50.

Vernon King Stevenson Earthman, Shelbyville, Tenn.; Vanderbilt University School of Medicine, Nashville, 1893; member of the Tennessee State Medical Association; veteran of the Spanish-American War and World War I; on the staff of the Rutherford Hospital, Murfreesboro; died August 8, aged 72, of coronary occlusion.

Charles Edward Eaton, Stanwood, Wash.; McGill University Faculty of Medicine, Montreal, Que., Canada, 1904; member of the Washington State Medical Association; served during World War I; died at Camano Island August 21, aged 69.

Frank George Engelhardt, Syracuse, N. Y.; Syracuse University College of Medicine, 1892; veteran of the Spanish-American War; died August 18, aged 73, of carcinoma of the esophagus and stomach.

Wallace J. French, Pike, N. Y.; University of Buffalo School of Medicine, 1884; member of the Medical Society of the State of New York; health officer of the town of Pike; on the staff of the Wyoming County Community Hospital, Warsaw; died August 30, aged 85, of cerebral hemorrhage.

Alphonse Paul Gagnon, Taunton, Mass.; Tufts College Medical School, Boston, 1921; member of the Massachusetts Medical Society and the American Society of Anesthetists, Inc.; served an internship at the Fall River City Hospital, Fall River; examining physician of Selective Service Board num-

ber 148; formerly tuberculosis diagnostician of the board of health and chief of the staff of the Bay View Hospital in Fall River; on the staff of the Morton Hospital, where he died August 2, aged 52.

Clarence William Graser, Buffalo; University of Buffalo School of Medicine, 1918; member of the Medical Society of the State of New York; died in the Millard Fillmore Hospital August 20, aged 48, of cirrhosis of the liver.

Edward Melvin Green ♂ Harrisburg, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1890; member of the American Psychiatric Association; fellow of the American College of Physicians; member, medical advisory board, Pennsylvania Selective Service; formerly on the staff of the Georgia State Sanitarium, Milledgeville; consultant in psychiatry and administration and for many years superintendent of the Harrisburg State Hospital; died September 30, aged 76.

Ralph Hagan, Los Angeles; University of Southern California College of Medicine, Los Angeles, 1895; formerly police surgeon; served during World War I; on the staff of St. Vincent's Hospital, where he died August 20, aged 72, of angina pectoris.

John Albert Hagemann ♂ Pittsburgh; Columbus Medical College, 1884; member of the American Academy of Ophthalmology and Otolaryngology; specialist certified by the American Board of Otolaryngology; formerly on the staff of the Pittsburgh Hospital; died July 15, aged 81, of pneumonia.

Thomas J. Heavey, Medway, Mass.; Middlesex College of Medicine and Surgery, Cambridge, 1922; member of the Massachusetts Medical Society; died August 7, aged 58.

Harry Joseph Hill, Waltham, Mass.; College of Physicians and Surgeons, Boston, 1910; formerly a medical missionary in China; served during World War I; at one time on the staff of the Northampton State Hospital, Northampton; a member of the staff of the Metropolitan State Hospital; died August 6, aged 59, of cerebral thrombosis, general arteriosclerosis and diabetes mellitus.

Thomas Milton Hood, Clarksburg, W. Va.; Jefferson Medical College of Philadelphia, 1880; honorary member and in 1905 president of the West Virginia State Medical Association; twice president of the Harrison County Medical Society; at one time assistant superintendent of the Weston State Hospital, Weston; on the staffs of the Union Protestant Hospital and St. Mary's Hospital; died, September 27, aged 91, of senility.

Lester Paul Hulick ♂ Mansfield, Ill.; St. Louis University School of Medicine, 1925; served an internship at the Missouri Baptist Sanitarium, St. Louis; on the staff of the John and Mary E. Kirby Hospital, Monticello; died, August 20, aged 45.

Elmer C. Huselton, Pittsburgh; Jefferson Medical College of Philadelphia, 1884; formerly on the staff of the old Allegheny General Hospital; died August 24, aged 84, of heart disease.

Leon Downie Jay ♂ Waverly, Iowa; State University of Iowa College of Medicine, Iowa City, 1910; fellow of the American College of Surgeons; on the staff of the St. Joseph Mercy Hospital; died August 8, aged 58, of cerebral hemorrhage.

William Robert King, Minneapolis; Harvard Medical School, Boston, 1917; served an internship at the Peter Bent Brigham Hospital, Boston; on the staff of the Abbott Hospital; died August 10, aged 54, of cerebral hemorrhage.

Silvanus B. Kirkpatrick, Taylor, Texas; Missouri Medical College, St. Louis, 1883; honorary member of the State Medical Association of Texas; died in the Stromberg Clinic and Hospital August 4, aged 92, of uremia.

Dantan Wyeth Landess, Port Allen, La.; University of Tennessee College of Medicine, Memphis, 1930; member of the Louisiana State Medical Society; served as health officer and coroner of West Baton Rouge Parish; a lieutenant colonel in the Louisiana State Guard, in which he had been commander of the seventh battalion; an organizer and past president of the Port Allen Lions Club; died in Our Lady of the Lake Sanitarium, Baton Rouge, August 21, aged 48.

Kevin David Lynch ♂ El Paso, Texas; Columbia University College of Physicians and Surgeons, New York, 1911; member of the American Urological Association; president-elect and formerly vice president of the Southwestern Medical Association; served in France during World War I; on the staffs of the Hotel Dieu, Sisters' Hospital, Providence Hospital and the Southwestern General Hospital; died June 2, aged 58, of hypertensive heart disease.

Horace Cuilford MacKerrow, Worcester, Mass.; Leonard Medical School, Raleigh, N. C., 1904; University of Bishop College Faculty of Medicine, Montreal, Que., Canada, 1905; died in the Palmer Memorial Hospital, Boston, August 14, aged 64, of metastatic adenocarcinoma from the biliary tract.

Rufus Henry Main, Barry, Ill.; Missouri Medical College, St. Louis, 1894; member of the Illinois State Medical Society and its "Fifty Year Club"; for eighteen years secretary of the Pike County Medical Society; for many years member of the school board; died August 20, aged 76.

Daniel Joseph Maloney, Waterbury, Conn.; New York University Medical College, New York, 1896; past president of the Waterbury Medical Association; on the staffs of the Waterbury and St. Mary's hospitals; died August 4, aged 77, of carcinoma of the stomach and general arteriosclerosis.

Herman Gustave Maul @ Denver; Denver and Gross College of Medicine, 1910; Army Medical School, 1915; member of the American Roentgen Ray Society and the Radiological Society of North America, Inc.; formerly an officer in the medical corps of the U. S. Army; major, medical reserve corps, U. S. Army, not on active duty; died August 13, aged 57, of injuries received when caught by a power saw.

Caesar Peele McClendon, New Rochelle, N. Y.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1903; died in Wells, Maine, August 31, aged 68, of heart disease.

Joseph N. Moore, Marshall, N. C.; University of North Carolina School of Medicine, 1905; for many years county physician; served as a member of the board of directors of the Aston Park Hospital, Asheville; died August 21, aged 60, of chronic myoearditis and carcinoma of the prostate.

Andrews Rogers, Columbus, Ohio; Columbia University College of Physicians and Surgeons, New York, 1901; since 1943 professor emeritus of obstetrics at the Ohio State University College of Medicine, where he had been professor from 1916; specialist certified by the American Board of Obstetrics and Gynecology, Inc.; on the staffs of the Starling-Loving University Hospital, Mount Carmel Hospital, Franklin County Tuberculosis Hospital and the Grant Hospital; died August 6, aged 71.

Robert E. Ryle, Walton, Ky.; Starling Medical College, Columbus, 1896; member of the Kentucky State Medical Association; died August 30, aged 72, of myocarditis and arteriosclerosis.

John Gibson Sargent, Centralia, Wash.; State University of Iowa College of Homeopathic Medicine, Iowa City, 1908; died July 26, aged 68.

CAPT. LEO E. APANASEWICZ
M. C., A. U. S., 1915-1944

CAPT. JACOB T. FARRIS
M. R. C., U. S. Army, 1916-1944

Henry Damon Smith @ Sanford, Fla.; University of Alabama School of Medicine, 1912; twice president of the Seminole County Medical Society; died August 12, aged 54.

William S. Steele, Bluefield, W. Va.; Baltimore University School of Medicine, 1893; died August 20, aged 76, of hepatitis.

Charles Nicholas Stroube @ Roachdale, Ind.; University of Louisville Medical Department, Louisville, Ky., 1897; died suddenly, September 17, aged 75, of coronary occlusion.

George Edwards Tooley, Seattle; Marion-Sims College of Medicine, St. Louis, 1901; member of the House of Delegates of the American Medical Association in 1908; formerly chief medical officer of the Veterans Administration Facility in Wichita, Kan., and on the staff of the Veterans Administration Facility in Lincoln, Neb.; served during World War I; died in August, aged 68, of myocardial infarct.

Herman Luther Tutwiler, Patterson, Va.; Medical College of Virginia, Richmond, 1900; member of the Medical Society of Virginia; formerly vice president of the McDowell (W. Va.) County Medical Society and member of the West Virginia state legislature; died July 29, aged 71.

William Franklin Waggoner, Carrollton, Ill.; Barnes Medical College, St. Louis, 1903; member of the Illinois State Medical Society; on the board of the Boyd Memorial Hospital; died in Macon, Mo., July 14, aged 77.

Thomas Francis Welch, Hartford, Conn.; Georgetown University School of Medicine, Washington, D. C., 1904; member of the Connecticut State Medical Society; president of the Hartford Medical Society in 1932; served as a member of the draft board of Hartford during World War I; member and past president of the staff of St. Francis Hospital; died July 19, aged 71, of cerebral thrombosis.

Cephas John Wells @ Bartlesville, Okla.; Louisville Medical College, 1894; died September 9, aged 79, of congestive heart disease.

James Alexander White, Alexandria, La.; College of Physicians and Surgeons, Baltimore, 1892; member of the Louisiana State Medical Society; member of the board of directors and treasurer of the Louisiana College, Pineville; on the staff of the Baptist Hospital; died May 23, aged 76, of coronary thrombosis.

James Johnston Withers, Davidson, N. C.; Jefferson Medical College, Philadelphia, 1909; served during World War I; formerly a druggist; on the visiting staff of the Lowrance Hospital, Mooresville; died July 30, aged 64, of coronary occlusion.

KILLED IN ACTION

Leo Edwin Apanasewicz, Cleveland; St. Louis University School of Medicine, 1941; served an internship at St. John's Hospital; began active duty as a first lieutenant in the medical corps, Army of the United States, on July 25, 1942; later promoted to captain; served in the North African and Italian campaigns; died in an army hospital in England, June 15, aged 28, of wounds received in Normandy on D day, June 6.

Jacob Thomas Farris, Richmond, Ky.; Vanderbilt University School of Medicine, Nashville, Tenn., 1940; served

an internship in pediatrics at the Strong Memorial Hospital and the Rochester Municipal Hospital, Rochester, N. Y.; commissioned a first lieutenant in the medical reserve corps of the U. S. Army in June 1940; began active duty on Aug. 25, 1941; promoted to captain in January 1943; stationed at hospital in Fort Knox, Kentucky, for one year and trained in various other posts in the U. S. Army before going overseas early in January 1944; landed with the invasion troops in Normandy on D day; twice cited for bravery and awarded the Silver Star; killed in France by shrapnel severing his spinal cord August 3, aged 27.

Bureau of Investigation

DANGEROUS TO HEALTH

Because of Inadequate Warnings on Labels

[Editorial Note—These abstracts concern preparations which were specifically declared by the Food and Drug Administration of the Federal Security Agency to be misbranded because their labels failed to carry adequate warnings against giving them to children, or using them in the pathologic conditions in which they might be dangerous to health, or to caution against unsafe dosages or methods or duration of administration or application, for the protection of the user. The abstracts that follow are given in the briefest possible form: (1) the name of the product, (2) the name of the manufacturer, shipper or consigner, (3) the date of shipment, (4) the composition, (5) the type of nostrum, (6) the reason for the charge of misbranding, and (7) the date of issuance of the Notice of Judgment.]

Aurofectol Purpoil No 22 and Purpoil No 600—Purpoil Laboratories Inc., Baltimore. Shipped March 9 and 25 1942. Composition Aurofectol essentially a mixture of oils and phenols. Purpoil Nos 22 and 600 both essentially mineral oil with small quantities of iodine chlorbutanol and menthol. Aurofectol adulterated because strength differed from that which label represented it to possess, since it was not an antiseptic. Misbranded because label falsely represented that product would be efficacious in treating dermatitis, eczema, acute catarrhal inflammation of tympanic membrane, acute and chronic infections of external auditory canal, acute myringitis and catarrhal otitis media, that it was an effective parasiticide and antiseptic in skin diseases and would produce desired results in treating infections of the skin of the external auditory canal. Purpoil products misbranded because labels failed to warn adequately against use by children or in those conditions wherein products might be dangerous to health since frequent or excessive use might cause injury to the lungs. Purpoil No 22 further misbranded because label falsely suggested that product was in effective treatment of acute and mild chronic infections of the nose, would cause a depletion of the swollen mucous membrane, promote drainage greatly improve ventilation and gradually diminish excess discharge, regardless of its cause. Both Purpoil products also misbranded because falsely represented to have bacteria destroying properties equivalent to phenol in the same strength and in the same type of oil. Purpoil No 600 specially misbranded because of false statement "Used in the treatment of chronic suppurative infections of the nose."—[D D N J, F D C 759, September 1943]

Lueberl's Iron Tonic Compound Tablets—A. G. Luebert, Wilmington Del. Shipped May 17 and June 27, 1941. Composition essentially salts of iron and manganese strychnine sulfate arsenic trioxide, a phosphide, and fish oil. Misbranded because label failed to warn against giving product to children and elderly persons in view of strychnine content, or to caution against taking more than the recommended dose and against frequent or continued use because of strychnine and arsenic content, further misbranded because of label misrepresentation that product would produce rich blood, good health, strong nerves and astounding vitality, give strength and vigor to the entire system, cleanse the blood after accumulations of winter months, benefit the weak run down or depressed produce proper activity of all organs and functions of the body, stimulate the nutritive functions, tone the digestive tract and benefit those conditions which call for an effective tonic such as loss of appetite and a tired, run-down feeling. Further misbranded because of false representation that these tablets were solely an iron tonic since they contained some additional drugs that were physiologically active also misbranded because label failed to declare quantity or proportion of strychnine sulfate and arsenic trioxide.—[D D N J, F D C 754, September 1943]

Pond's Digestans and Pond's Laxative Pills—Pond Pharmaceutical Company, Inc. New York. Shipped Oct 8 and Nov 13, 1941. Composition Digestans essentially sodium bicarbonate peppermint oil strychnine sulfate and extracts of laxative plant drugs including aloin laxative Pills essentially laxative plant drugs (including aloin and podophyllin) and small amounts of belladonna. Both articles misbranded because directions for use were inappropriate and inadequate for a laxative since they provided for continued administration which might establish the laxative habit further misbranded because, though label cautioned user against taking laxatives in the presence of nausea vomiting and abdominal pain it failed to warn that such symptoms may be those of appendicitis, also misbranded because tablets contained strychnine but labeling failed to warn that not more than the recommended dosage should be taken and that use by children and elderly persons might be especially dangerous, misbranded further because warnings required by law were not conspicuous on the label. Misbranded again because of certain label misstatements regarding the action of ingredients of Digestans and because the Laxative Pills were not properly labeled as to active ingredients and quantity of contents.—[D D N J, F D C 764, September 1943]

W K Steriline's Compound—Walter K. Steriline trading as W. K. Steriline, Sidney Ohio. Shipped Dec 30, 1940. Composition alcohol 15 volume 75 per cent and in each fluid ounce 15.25 grains of potassium iodide and 14.40 grains of sodium bromide. Misbranded because label failed to bear adequate warnings against giving to children or taking it in the pathologic conditions wherein it might be dangerous to

health or against unsafe dosage, since, because of presence of potassium iodide, it should not be taken in cases of lung disease chronic cough or goiter, and should be discontinued if a skin rash should appear, frequent or continued use might lead to mental derangement, skin eruptions or other serious effects. Also dangerous to health because, considering presence of sodium bromide, product should not be used by those suffering from kidney disease. Misbranded, also, because labels failed to state that product should not be administered to children under 6 years of age, and because they falsely declared the amounts of alcohol, potassium iodide and sodium bromide present.—[D D N J, F D C 806, December 1943]

STIPULATIONS

Agreements Between Federal Trade Commission and Promoters of Various Products

Following are abstracts of stipulations in which promoters of "patent medicines," medical devices and cosmetics have agreed, following action by the Federal Trade Commission, to discontinue certain misrepresentations in their advertising. These stipulations differ from the "Cease and Desist Orders" of the Commission in that such orders definitely direct the discontinuance of misrepresentations. The abstracts that follow are presented primarily to illustrate the effects of the provisions of the Wheeler-Lea Amendment to the Federal Trade Commission Act on the promotion of such products.

Casafra—In February 1944 Leo J. Dunn, trustee trading as Mason Drug Company, Boston, entered into a stipulation with the Federal Trade Commission regarding this product. In this he agreed to discontinue any advertisement which did not reveal that Casafra should not be taken when abdominal pain, nausea or other symptoms of appendicitis are present. It was provided however, that future advertisements need contain only the statement "Caution: Use Only as Directed" if the instructions for use on the label should contain a warning to the same effect.

Dr. Edgar Health Shoes and Dr. Edgar Health Cushion Shoes—In March 1944 A. J. Schoenecker and Margaret Wenhse, co-partners trading as A. J. Schoenecker Shoe Company, Milwaukee, stipulated with the Federal Trade Commission that they would no longer use the descriptions "Dr. Edgar Health Shoes" and "Dr. Edgar Health Cushion Shoes" in advertising branding or labeling the shoes that they sell, or the word "Doctor" or its abbreviation, either alone or with the word "Health," so as to imply that their shoes have been made in accordance with the design or under the supervision, of a physician, or contain special scientific orthopedic or health features which are the result of medical determination or services. They further agreed to discontinue representing through use of the word "Manufacturers" that they make the shoes that they sell or own and operate or directly and absolutely control the factory in which their shoes are made.

Hennafoam Shampoo—This is put out by Alfred Horowitz trading as Hennafoam Shampoo Company, New York City. In February 1944 he stipulated with the Federal Trade Commission that he would cease representing that the product has been tested, or tested and approved by Good Housekeeping Magazine or any other organization which it owns or controls unless the tests have been made in such manner as to give reasonable assurance of its quality, nature and properties in relation to its intended use and to the fulfillment of the claims made for it.

Kondremul with Non-Bitter Extract of Cascara and Kondremul with Phenolphthalein—These are products of the E. L. Patch Company, Boston. In February 1944 this concern entered into a stipulation with the Federal Trade Commission to discontinue any advertisement which did not reveal that the preparations should not be used when abdominal pain, nausea or other symptoms of appendicitis are present. It was agreed however that it would be sufficient for future advertisements to contain the statement "Caution: Use Only as Directed" if and when the directions for use on the labels should carry a warning to the same effect.

Lashgro—This is promoted by Bertrice Kornstein trading as Avalon Lane Company, New York. In February 1944 she stipulated with the Federal Trade Commission that she would cease representing by use of the trade name "Lashgro" or otherwise that her product causes the eyelashes to grow longer or thicker will promote or in any way affect their growth or correct or remedy red, sandy eyelids.

Stevens' Mineral Water, Stevens' Concentrated Mineral Water, and Stevens' 50-50 Water—These were the subjects of a stipulation entered into with the Federal Trade Commission in March 1944 by F. A. Stevens of Dawson Springs, Ky., in which he agreed to discontinue the following misrepresentations in the advertising: That these waters are in effective treatment or relief for stomach trouble, acute or chronic nephritis, uremia, engorged liver or kidney, rheumatism, gout, gall stones, dropsy, appendicitis and some other ailments; that the waters are a cure for chronic constipation or a treatment for that condition in excess of temporarily relieving it; or that the physiologic effects of the preparations are greater than those of a saline laxative and a weak antacid. He further agreed to discontinue any advertisement which represented that the use of these waters was safe, or which failed to reveal the potential danger in using them when abdominal pains, nausea or other symptoms of appendicitis are present. The stipulation provided however that when the potential danger in their use was noted on the label, a advertisement need contain only the warning "Caution: Use Only as Directed."

Correspondence

POWDER FOR SURGICAL GLOVES

To the Editor—An editorial in THE JOURNAL, September 23 entitled "Exit Talcum from the Surgical Scene" has provoked considerable comment among industrial hygienists. There you make the statement that "These lesions [the talc granulomas] are permanent because the body does not have adequate reparative power against talcum, which is essentially a silicate and which therefore induces a silicosis."

I would question the validity of the assumption that a silicate can cause silicosis, and several people have already written me to protest against your generalization. All experimental evidence derived from study of pure silicates indicates that as a class these minerals do not dissolve within the body to liberate their component silica with resultant fibrosis. In fact most of the silicates are inert materials and only a few of them, like asbestos and possibly mica, may be irritating because of peculiar physical properties. These experimental results, based on the study of pure minerals, are not always applicable to the mixtures encountered in industry. Many dusts are named for their major component but analysis reveals that they contain significant quantities of quartz that may be responsible for pulmonary reactions noted in chest roentgenograms.

In the case of talc I know that contamination with quartz is responsible for some of the alleged reactions in the lungs. In other instances nomenclature is at fault and the inhaled minerals actually consist of mixtures of tremolite, anthophyllite (both fibrous silicates), serpentine and either granular or fibrous talc. The fibrous minerals produce the peculiar bodies found in asbestosis and, in my opinion, pulmonary reaction to these so-called "talc" is due to their fibrous structure rather than to their silica content. They produce granulomas only when the particles are fairly large, 20 microns or more in length. Grinding them to 3 microns or less in maximum diameter renders them comparatively inert so that tissue reaction is limited to simple phagocytosis. With crystalline silica, whose action is known to be chemical, the reverse is true and the finer the quartz the more irritating it becomes.

The talcum powder granulomas of the peritoneal cavity are obviously foreign body tubercles, for all observers have mentioned the detection of refractile mineral particles. The size of these particles is not usually mentioned, but they must obviously be quite large to be detected under the biologist's polarizing microscope. Petrographic examination of one commercial talcum for hospital use revealed particles and fibers ranging in size from 150 microns downward. This material consisted of fibrous tremolite and particulate talc, dolomite and serpentine. Other samples contained varying amounts of quartz. Experiment demonstrates that intraperitoneal injection of the untreated powder will produce foreign body tubercles, after regrinding to size 3 microns and under (the size at which quartz exerts its specific effects) intraperitoneal reaction is limited to phagocytosis. Fibrosis develops only about large accumulations of the powder, and this is a nonspecific reaction against the mass of foreign body. Regardless of particle size reactions to talc are not progressive.

For the reasons cited I cannot subscribe to your explanation of the talc granuloma. "Reparative power" is involved only in the sense that the tissues have walled off an insoluble foreign body. I can discover no reason for considering such reaction an attempt to repair a chemical injury. The hypothesis that body fluids attack silicates and leach out the bases to leave silica in active form finds no support in controlled experimental observation.

LEROY U. GARDNER, M.D., Saranac Lake, N. Y.

Director, Saranac Laboratory for Study of Tuberculosis

To the Editor—I have been much interested in the discussion going on for some time about a substitute for talcum powder in operating room gloves.

Why do we need any substitute? If gloves are dry and hands are dry, as they should be, and the gloves are the right size, any foreign material unnecessarily introduced into the field is an added danger. I have been wearing rubber gloves in the operating room for over forty years and have never used any kind of glove powder. In these days of constantly changing operating room nurses I have to be on the alert to escape the avalanche of talcum with which I am constantly threatened, but so far I have valiantly held my ground and have gone into the operating room with fingers that are cleaner and have a better tactile sense.

This tendency to get rid of an evil thing by substituting another evil thing is a common fault in everyday thinking. There is no need to have a substitute for a nuisance.

DANIEL THOMAS QUIGLEY, M.D., Omaha

'GETTING PATIENTS OUT OF BED EARLY IN THE PUERPERIUM'

To the Editor—On page 839 of THE JOURNAL of July 22 Dr. Morris L. Rotstein of Baltimore makes the statement that during the blitz of 1940-1941 London maternity patients delivered in hospitals were allowed up a day after labor and sent home on the second or third day post partum. He adds that "no ill effects resulted from this mode of treatment."

It would seem that Dr. Rotstein is under some misunderstanding, for although one half of the institutional confinements in London take place in hospitals directly under my control and I am in close touch with the voluntary hospitals responsible for the remaining institutional births in London, I have never heard of such a routine. The true facts may interest your readers. During the whole war period, all expectant mothers who could be persuaded to leave London were evacuated at the eighth month to country maternity homes organized by the Ministry of Health and there they were retained until the usual fourteen days after confinement. At the end of this period they were discharged to country billets with their infants, but many returned soon after to their homes in London, especially if the blitz was not active.

Of the mothers who could not be persuaded to leave London those who were normal medically and whose homes were suited for confinements were expected to have their babies at home. This is the usual prewar custom in England, and we did not depart from it during the blitz, but of course enemy action rendered many houses unsuitable and added to the pressure on our beds. Further, all hospitals retained the fourteen day period during the early part of the war, but many (including the London County Council's hospitals) were obliged to reduce the mothers' stay to ten or twelve days as accommodation was reduced by bombing or by necessary air raid precautions. Any woman who had to be sent home earlier (which very rarely happened and never before the seventh day) was conveyed by ambulance and a visiting nurse was sent to care for her. It is also true that in two areas of London where hospital accommodation became very short the women were (and are still) transferred by ambulance to a suburban hospital with excellent accommodation on the fourth day, but they are not expected to go home till the twelfth day. No bad effects have been reported but the arrangement is much disliked by the women and will be abandoned directly events permit. It is probably a garbled version of this plan which has reached Dr. Rotstein.

May I add that we have had many attempts in the last forty years to introduce a shortened puerperium into English mid-

where practice but they have never taken hold. The present tendency is to insist more firmly than ever on six to seven days in bed and a total fourteen days of rest and exemption from household duties with a longer convalescence still after complicated confinements. The value of graduated physical exercises during the antepartum period and from the third or fourth day of the puerperium is of course widely appreciated.

ALLEN DALEY, M.D.,
Medical Officer of Health, London County Council

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Chiropractic Practice Acts: Revocation Proceedings Not Barred by Failure of the Licentiate to Renew License.—The state of Iowa in February 1943 instituted proceedings to revoke Otterholt's license to practice chiropractic in Iowa charging that the chiropractor was guilty of wilful and repeated violations of the Iowa laws relating to the practice of the healing arts. It was alleged that the chiropractor had repeatedly not confined his practice to chiropractic and had treated his patients "with electric and other machines which is not the proper practice of chiropractic but is the practice of medicine and surgery for which he has no license." It was also alleged that the chiropractor was guilty of fraud and misrepresentations as to his skill and ability "in using a machine termed a 'Pathoclast' of no therapeutic value and falsely representing its therapeutic value." The chiropractor moved to dismiss the action, questioning the authority of the state to institute the action and the constitutionality of the state laws relating to the healing arts. Under the applicable Iowa law every license to practice a profession expires annually on the 30th day of June but can be renewed without examination on application accompanied by the legal fee at least thirty days prior to the expiration of the license. The chiropractor permitted his license to expire and did not apply for a renewal thereof. Subsequently he amended his motion to dismiss and contended that since he no longer was licensed to practice the action should be dismissed because the question of cancellation of his license was now moot. The trial court sustained the motion "on ground that cause of action has ceased to exist." The state accordingly appealed to the Supreme Court of Iowa.

The chiropractor said the Supreme Court, had the right to practice chiropractic by virtue of the license granted by the state acting under its police power. Such practice involves the health and safety of the citizens of the state and practice under such license is subject to all reasonable conditions and regulations. Among such conditions is the requirement of annual renewal. This court on many occasions has sustained the right of the state to regulate the practice of the healing art and the constitutionality of the laws on the subject now in force. Through the license to practice granted the chiropractor by the state subject to the regulations referred to the chiropractor is the possessor of a valuable privilege or right "which cannot be denied or abridged in any manner except after due notice and a fair and impartial hearing before an unbiased tribunal" (*Gilchrist v. Burring* 14 N. W. (2d) 724). The state cannot by issuing only annual licenses ingeniously thwart those precious rights and once an annual license is issued to a [licentiate] unless he has violated some of the provisions of the statute applicable to his profession he is entitled to the renewal of his license as a matter of right.

The Supreme Court did not agree with the holding of the trial court that the cause of action against the chiropractor had ceased to exist when the chiropractor failed to renew his license. There is a marked difference said the court between a license to practice a profession and a mere renewal of that license. As was said by this court in *Gilchrist v. Burring* supra

This is because a dental doctor lawyer or the member of any other profession does not devote the years of study and preparation necessary to qualify as a practitioner merely that he may be accorded the right to practice for one year. When he qualifies for the practice, he does so for life. That right cannot be taken from him except by due process of law.

The certificate entitling the chiropractor to practice is a finding by the duly constituted authority that he has the necessary character and qualifications to practice chiropractic. The mere failure to renew annually does not lessen the value of that license except for the lapsed period before the renewal. The chiropractor is still the owner of the license and may be reinstated and continue the practice of chiropractic without examination, subject as always to the supervisory power under which he previously exercised it such right to practice being evidenced by its renewal. All benefits of his license did not expire on July 1 1943. His rights under the original license are of value. To deprive him absolutely and finally of the right ever to practice is much more serious than the mere suspension of that right, either voluntary or compulsory. Contrary to the procedure in renewal, in which one who is not an offender against the rules regulating the practice is entitled to a renewal as a matter of right one who has had his license revoked must commence anew by making an original application for another license. *Hanson v. State Board of Medical Examiners* 220 Iowa 357, 260 N. W. 68.

We do not consider the question involved moot, merely because the chiropractor is not at present making full use of his license to practice. As stated in 3 American Jurisprudence 366.

It may be noted that the question whether a provision in a decree confers a particular right upon a party is not rendered moot on appeal merely because such party testified at the trial that he did not expect to exercise such right.

To hold otherwise places in the hands of the accused practitioner himself the power to escape the penalty provided by law for a violation of the rules governing the conduct of his practice, no matter how gross his misconduct may have been. The cause of action has not ceased to exist so long as there remain rights undetermined and all matters involved in the action have not been adjudicated. We are satisfied that the cause of action has not ceased to exist.

The Supreme Court accordingly ordered the cause to be returned to the trial court for trial on the merits—*State v. Otterholt* 15 A. 11 (2d) 520 (Iowa 1944).

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1934 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Electrocardiographic Changes in Coronary Occlusion and Postoperative Pericarditis.—Bayley and La Due describe experiments on dogs which were devised to test the interpretation offered by Blumgart and his co-workers concerning the "prolonged" electrocardiographic changes associated with experimental temporary occlusion of a coronary artery. The authors present a method by which the electrocardiographic changes due to experimental coronary occlusion may be differentiated from those caused by the associated postoperative pericarditis. They show that the changes in the final ventricular deflections which are due to experimental temporary coronary occlusions of fifty minutes or less vanish completely within thirty minutes after cessation of occlusion and that the changes which appear on and after the first postoperative day are caused by local postoperative pericarditis. The duration of the electrocardiographic changes which immediately follow cessation of occlusions of fifty minutes or less is directly proportional to the duration of the occlusion. There are no differences in the magnitude or in the kind of electrocardiographic changes which are produced by acute local ventricular ischemia and injury, on the one hand, and by local postoperative pericarditis, on the other. The former occur during and for a brief time after temporary occlusion. For the most part the latter occur on and after the first postoperative day. The site of generation of the electrical effect which account for the two etiologically different groups of changes is different, i. e. the electrical effects associated with occlusion are generated in the muscle ordinarily irrigated by the occluded artery, whereas those associated with postoperative pericarditis are generated by the muscle adjacent to the local epicarditis which results primarily from the trauma of dissection of the coronary artery and from the trauma caused by the sutures which are used to close the pericardial sac. These observations differ decidedly from those of Blumgart and his co-workers. The authors ascribe the differences to the use by the other investigators of extremity leads only. It is important not to rely entirely on extremity leads for an evaluation of the electrocardiographic changes which occur in association with animal experimentation.

Sulfonamide Concentrations in Blood.—The experiments by Welch and his collaborators were designed to compare concentrations of sulfonamide produced in the blood of normal human subjects by daily administration of a single small dose of sulfamerazine, sulfadiazine, sulfamethazine or sulfathiazole. Observations were made on the average sulfonamide concentrations produced in the blood of 8 normal men by daily 1 Gm. doses of these drugs. The concentration in the blood following maintenance doses of sulfamerazine fell from a daily maximal value of about 6.5 to a minimal value of about 3.5 mg. per hundred cubic centimeters, with sulfadiazine from about 3.5 to about 1.5, with sulfamethazine from about 4 to less than 1, and with sulfathiazole from about 2 to less than 1 mg. per hundred cubic centimeters. Sulfamerazine administered in single 0.5 Gm. daily doses maintained a concentration in the blood which fell gradually from a level of approximately 4 to a level of about 2 mg. per hundred cubic centimeters. Emphasis is placed on the rapid absorption and gradual elimination of sulfamerazine, which make possible the maintenance of a concentration in the blood, with single daily doses of only 0.5 to 1 Gm., that is probably sufficient for certain chemoprophylactic purposes. The data presented, as well as clinical experience with sulfamerazine, indicate that adequate therapeutic concentrations in the blood should be maintained by the administration of smaller total daily doses than with other sulfonamides; these doses can be given on the basis of only two or three divided doses daily.

Significance of Great Left Axis Deviation.—While it is generally recognized that moderate deviation of the electrical axis of the heart to the left is a common finding in normal persons, its frequency approximating 20 per cent, there appears to be little agreement as to the significance of the less frequent but by no means rare pattern of great left axis deviation in which S_2 is of greater amplitude than R_2 . Faulkner and Duncan studied clinical records of 200 consecutive cases exhibiting this pattern. The records revealed that 51.5 per cent had no left ventricular enlargement. Measurements of the heart from teleroentgenograms in 97 cases were within normal limits in 35. The heart was normal anatomically in 8 of 27 cases subjected to necropsy. There was a definite increase in the incidence of the pattern in the older age groups. The authors conclude that great left axis deviation in an otherwise normal electrocardiogram is a normal variation which, though encountered with increasing frequency with advancing age, cannot be correlated with ventricular enlargement, coronary disease or myocardial disease.

Continuous Caudal Anesthesia in Acute Pelvic Thrombophlebitis—During the past six months Ellis and Sheffery have used continuous caudal anesthesia in 10 cases of acute pelvic thrombophlebitis with excellent results. Two typical cases are reported. The authors feel that the caudal method has several advantages over the regional sympathetic block of the first, second, third and fourth lumbar sympathetic ganglions. Regional injection requires four punctures, caudal but one. The continuous bathing of the sympathetic chain for several hours is preferable to the one injection technique necessitated by the regional block method. In caudal nerve block it is possible to tell when the needle is correctly placed by the classic signs such as sciatic pain, progressive regional anesthesia, sphincter relaxation and vasodilatation of the extremities. In sympathetic nerve block one cannot be sure that all the ganglions have been correctly injected. In acute thrombophlebitis the authors give 30 cc (low caudal) every hour until four doses have been given. This intermittent method of injection has the advantage that, if there is a tendency for the vasoconstriction to reestablish itself after the effect of the drug wears off, the impulse can be immediately released again by the next injection.

Vitamin C and Ability to Work in Hot Environments.

—According to Henschel and his associates claims have been made that large ascorbic acid intakes are of immediate benefit in exposures to high temperature of relatively short duration. The authors report 3 series of studies on 44 normal young men under rigidly controlled conditions of diet, physical work and environment. The ascorbic acid intake was set at two levels: 20 to 40 mg and 520 to 540 mg. Particular attention was paid to (a) cardiovascular functions, (b) performance of standard physical tasks, (c) psychomotor functions and (d) ascorbic acid in sweat, blood plasma and urine. The performance of muscular work was studied in dry heat up to 122 F. The stay in the heat varied from three hours to four days. Comparisons were made between performances on a diet restricted in ascorbic acid intake and a diet supplemented by 500 mg of ascorbic acid daily. The dietary differences were maintained for periods of four to seven days. Pulse rates in rest and in work, rectal temperatures, vasomotor stability tests, rates of sweating, general observations and subjective reports all failed to demonstrate significant advantage for the men receiving supplements of ascorbic acid. Psychomotor tests and strength tests likewise failed to show any advantage in the ascorbic acid supplementation. There apparently was a slight gain in flicker fusion frequency related to the extra intake of vitamin C. Daily sweat losses were 5 to 8 liters, but the total loss of vitamin C in the sweat is negligible. Heat exhaustion occurred with equal frequency in the vitamin C restricted and supplemented groups.

New Method of Treating Tetanus—Stern points out that the hematoencephalic barrier may prevent certain therapeutic substances from reaching the nerve centers. She proposed to treat tetanus by injecting the antitetanus serum into the cerebrospinal canal through a cisternal puncture. Precautions must be taken to force the solution under predetermined pressure into the ventricles by inserting the needle at a proper angle to prevent the fluid from flowing into the subarachnoid space. Injection of the serum into the subdural or subarachnoid spaces does not produce the desired effect, as the serum then returns to the blood stream without affecting the nerve centers. Animal experiments and veterinary practice demonstrate that when the symptoms of tetanus are manifest serum should be injected not only intramuscularly or intravenously but also into the ventricles by cisternal puncture. She usually injects 15,000 American units by cisternal puncture and from 30,000 to 50,000 American units intravenously or intramuscularly. This course may be repeated if necessary, but it is usually adequate. For the cisternal injection the patient is placed in a modified Trendelenburg position with the head somewhat lower than the body. At the moment of puncture the head is brought forward so that the chin rests on the sternum. The occipital protuberance and the spine of the atlas are palpated as landmarks. The needle is inserted at an acute angle between the two points and

directed inward in the midline. This point places the needle in the first cervical interspace. Resistance is felt at the dura. A relationship has been found to exist between the circumference of the patient's neck and the average depth of puncture. A neck circumference of 40 cm. corresponds to a puncture depth of 49 mm., a neck circumference of 39 cm. to a puncture depth of 47 mm., and so on. After from 10 to 20 cc. of cerebrospinal fluid has been withdrawn, an equal quantity of antitetanus serum warmed to body temperature is introduced. Six cases are described in which this method was used. As a rule, signs of lockjaw began to disappear twenty-four hours after cisternal injection of antitetanus serum. In cases of incipient tetanus a single cisternal injection of the serum was enough to control further development of the process, to effect a general improvement and to mitigate the symptoms of tetanus.

Syphilis and Pulmonary Tuberculosis.—Hoffman and Adams report the results of serologic tests for syphilis on 1,705 tuberculous Negroes admitted consecutively to a sanatorium. There were 507 with positive serologic reactions, an incidence of 29.7 per cent of coexisting syphilis and tuberculosis. The bases for comparison were the amount of pulmonary involvement and the predominant type of tuberculous lesion on admission and the percentage of deaths occurring in both groups in relation to the admission classification. There was no significant difference in the amount of pulmonary disease, the predominant type of tuberculous lesion or the percentage of deaths in the negative and positive serologic groups. The difference in the percentage of syphilis between the minimal and the far advanced tuberculosis groups was less than 7 per cent and could not be used to infer that syphilis lowered the resistance to tuberculosis. The presence of syphilis does not alter the course of pulmonary tuberculosis. Before a tuberculous patient is subjected to antisyphilitic treatment his tuberculosis prognosis must be good. The presence of pregnancy and syphilitic contagiousness are the only exceptions. Proof that the use of an arsenical causes tuberculosis to flare up in any 1 case is extremely difficult, if not impossible. The use of fractional doses of arsenicals, because of fear that full doses may activate tuberculosis, is empirical and defeats the purpose of the antisyphilitic treatment. The authors gained the impression that tuberculosis is hardly ever the cause of a false positive reaction.

Nutrition in Tuberculosis as Evaluated by Blood Analysis.—Getz and his associates report the results* of a nutritional study of 457 tuberculous and nontuberculous patients attending an outpatient chest clinic. Each assay included a determination of blood hemoglobin, serum proteins, plasma carotene, serum calcium, serum phosphorus and serum phosphatase, as well as plasma ascorbic acid, vitamin A and erythrocyte sedimentation rate. The authors correlate the analyses with the presence or absence and character of tuberculosis and of the individual deficiencies with one another. The subjects were men between 20 and 45. Men with active pulmonary tuberculosis were deficient in ascorbic acid, vitamin A, hemoglobin and serum albumin in the order listed. All nutritional deficiencies were more extensive and profound in tuberculous than in nontuberculous sub-

jects. Subjects with far advanced tuberculosis were especially deficient in ascorbic acid, serum albumin, hemoglobin, vitamin A, carotene and serum calcium in the order listed. Nontuberculous men from the same population group were deficient in ascorbic acid, hemoglobin, vitamin A and serum albumin, but to a lesser degree. Persons with arrested tuberculosis had nutritive levels essentially the same as nontuberculous men. There was more active tuberculosis in the oldest age group (40 to 49) and less of it was in the minimal stage than was found in the younger age groups. Age and hemoglobin showed a negative correlation; the hemoglobin level remained constant as the age advanced. Tuberculous and nontuberculous subjects alike had normal plasma levels of carotene in the presence of abnormally low vitamin A levels, a fact indicating that carotene conversion was inadequate. The plasma ascorbic acid level showed a positive correlation with the erythrocyte sedimentation test when the maximum five minute drop was used, but no correlation was observed when the total sedimentation in one hour was used. The erythrocyte sedimentation rate showed a positive correlation with the serum albumin concentrations. This fact is believed to give the sedimentation test new significance.

Sulfanilamide and Sulfapyridine in Experimental Tuberculosis.—Smith reports observations on four groups of guinea pigs. He found that sulfanilamide causes complete inhibition of tubercle bacillus cultural growth at a dilution of 1:1,000; sulfapyridine causes some inhibition at 1:5,000, complete at 1:1,000. Guinea pigs treated with 340 mg. of drug divided into five daily doses showed blood levels of 10 to 30 mg. per hundred cubic centimeters falling off to lows of 1 to 5 mg. per hundred cubic centimeters during the night. Sulfanilamide levels rose more rapidly than those of sulfapyridine but were less well sustained at night. Following infection with tubercle bacilli, the sulfanilamide and sulfapyridine treated animals were slower in the development of allergy than the controls. There was distinctly less tuberculosis in the sulfanilamide and sulfapyridine treated animals than in the controls and less in the sulfapyridine treated than in the sulfanilamide treated animals. These differences were shown by fewer and smaller tubercles in the visceral organs, by less caseation in viscera and internal lymph nodes and by smaller spleens and smaller internal lymph nodes. The average arbitrary units of disease per animal were 9.6 for the controls, 6.5 for the sulfanilamide treated and 4.2 for the sulfapyridine treated group. The local lesions, on the other hand, including sites of inoculation and inguinal lymph nodes, were as large in the treated as in the control groups or larger.

Glycosuria in Meningitis.—Ferguson and Barr reviewed records of 72 patients with meningitis admitted to New York Hospital, 30 of whom showed glycosuria. Fourteen of the 30 had received infusions of dextrose solution at some time before the appearance of glycosuria. In the remaining 16 patients cause for the glycosuria other than the meningitis itself was not evident. Glycosuria was encountered in meningitis caused by the meningococcus, the pneumococcus, the staphylococcus, the tubercle bacillus and in 1 case in which the causative organism was not isolated. Glycosuria was accompanied in many instances by ketosis, hyperglycemia and diminished tolerance to sugar. Glycosuria was transient, disappeared in all cases and persisted beyond the third day in only 3 of the 16 cases. Complications with glycosuria and ketosis at the onset of meningitis may mask

the signs of meningeal involvement, lead to a diagnosis of diabetic acidosis and cause serious or fatal delay in instituting appropriate treatment for the meningitis.

Sulfadiazine in Meningococcal Meningitis—Grieco and Cove review the clinical features of 20 consecutive cases of meningococcal meningitis observed in the course of a year at the Station Hospital, Fort Totten, New York. The cases were sporadic. Sulfadiazine and its soluble sodium salt was the only sulfonamide utilized. Polyvalent antimeningococcus serum was administered intravenously in 1 of the earliest cases in conjunction with chemotherapy. Such a severe reaction ensued that thereafter the use of serum was abandoned. As soon as the diagnosis was verified, an initial dose of 5 Gm of sodium sulfadiazine in 100 cc of distilled water was administered intravenously. Subsequent doses of 2 Gm were then given regularly every four hours for the next twenty-four hours either orally or intravenously, as determined by the patient's ability to ingest or retain the medication. Then 1 Gm doses were given every four hours until the temperature returned to normal, and from this point on four times daily for the next seven days. With this medication, adequate blood concentrations were attained and satisfactory clinical responses resulted. The Waterhouse-Friderichsen syndrome was diagnosed clinically in 1 case. The use of adrenal cortex extract was a life saving measure in this instance. This survival on substitutional therapy augurs well for this much dreaded complication. Two deaths resulted in this series of 20 cases. One occurred within less than twelve hours after the onset of the disease, the other four days after admission. Necropsy in the latter revealed a severe bilateral hemorrhagic necrosis of the adrenals.

Heterophile Antibody Reaction in Infectious Mononucleosis—The present concept is that there are three types of sheep cell agglutinins: those in normal serum absorbed by guinea pig kidney but not by beef erythrocytes, those in the serum of patients with infectious mononucleosis absorbed by beef erythrocytes but not by guinea pig kidney and those in the serum of persons treated with horse serum absorbed by both guinea pig kidney and beef erythrocytes. In this country the Paul Bunnell and Davidsohn methods are standard procedures. Kaufman describes changes made in the Davidsohn technique, the net result of which is that the test is simplified, is just as accurate and gives considerably quicker results. Telephoned reports can be given within one hour of the time of arrival of the serum in the laboratory, if speed of diagnosis is important, which it occasionally is in a questionable case of infectious mononucleosis thought to be acute appendicitis, meningitis, typhoid, mumps or diphtheria. So much time is saved by these modifications in technique that many more specimens can be examined in a day. During a three year period 83 proved cases of infectious mononucleosis have been investigated. In the diagnosis of this disease there are three aspects to consider: the clinical, the hematologic and the serologic. It is felt that if any two of them are definite the diagnosis may be considered established. Tests were performed in 78 of 83 cases of infectious mononucleosis. It is believed that agglutination in a dilution of 1:28 with the correct differential absorption tests is a positive reaction. A positive test supports the diagnosis of infectious mononucleosis, but a negative test does not rule it out. The reaction may become positive as early as the third day but sometimes not until the second month or not at all. The reaction usually remains positive for two to four months.

Breathing Therapy in Bronchial Asthma—Weiser treated asthmatic patients who had failed to respond to other treatments by breathing therapy. His intensified breathing therapy consists of massage, rhythmic compressions of the

thorax and breathing exercises. Intensive gymnastics are of special importance. These include sports (boxing, jujitsu, calisthenics) associated with regulated breathing. The exercises must be performed daily over a period of months or even years. Dyspnea is produced by physical strain during each treatment but with the aid of the acquired technique of respiration it is soon breathed away. The patient learns how to master dyspnea by concentration and regulation of respiration. Courage training, boxing, apparatus gymnastics and increased efforts during the course of treatments increase self confidence in the asthmatic patient. Intensified breathing therapy should be supervised by the physician. The vital capacity, expiration time and breathing span were always considerably increased during the course of treatments. The absolute value for vital capacity cannot be taken as a criterion for a prognosis. Prognostic conclusions can be drawn from curves derived from the vital capacity and expiration time measured during each treatment. In the study reported the minimum time of observation after treatment was twelve months. It was possible to keep 13 among 39 juvenile asthmatic patients free from attacks, they were under observation for three and one-half years. The disease in 10 of these 13 had lasted for more than two years before the treatment was instituted. Ten of the 29 children continued to show improvement. Six remained uninfluenced. Of 10 asthmatic adults, 1 was freed of attacks, 5 improved and 4 were not affected.

Early Ambulation Following Abdominal Section—Nelson reports observations on 426 personally conducted cases. As soon as the patient has fully recovered from the effects of anesthesia, the bed is sharply tilted, so that the head is elevated. After this position has been maintained for a time the bed is leveled and the patient assumes a sitting position on the side of the bed, with the feet resting on a chair. In this position he breathes deeply and coughs frequently. He then lies down, and the head of the bed is again sharply elevated. After a second period of rest he is assisted to stand and is conducted to the bathroom, where the bladder is practically always emptied without difficulty. If his condition is good he sits up in a chair for a time before returning to bed. Those who are oversensitive to the pain of the first rising or who are unduly apprehensive are made to practice sitting at the edge of the bed with intervals of rest after each attempt, until they are strong enough and willing to walk to the bathroom. The majority of patients walked on the day of operation or within the first twenty-four hours. The incidence of immediate and delayed complications in this series was minimal. Of the three partial disruptions of a wound two occurred in patients whose wounds had been closed with catgut and for whom early ambulation had not been authorized. Only two incisional hernias were observed. The single fatality in the series was due to cerebral thrombosis. Good results depend on the strict observance of contraindications as well as of indications. Contraindications to early ambulation are: 1. Failure to observe the prerequisites of optimum healing of wound including failure to carry out the tenets of Halsted as to the closure of a wound, the use of suture materials other than wire or cotton and the existence of deficiencies of vitamins and hypoproteinemia. 2. Conditions such as shock, peritonitis, active hemorrhage, cardiac failure, pneumonia and impending

or actual thyroid crisis 3 Potential or actual complications including gross contamination, infection, hemorrhage and dehiscence 4 Pregnancy in which abortion is feared 5 Extreme debility, for which ambulation is deferred until there is some restoration of strength and muscle tone, as a result of sitting up 6 Second stage of a thoracolumbar sympathectomy, after which the patient, because of sudden alterations in the vascular system, cannot immediately tolerate the upright position 7 Lack of adequate and intelligent nursing supervision The advantages of early ambulation include the lowered incidence of postoperative complications, particularly pulmonary and vascular complications, the lower incidence of nausea, vomiting and abdominal distention, the earlier return of normal function of the bladder and the bowel, the maintenance of normal muscle tone, the psychologic effect on the patient's morale and mental status, the acceleration of convalescence and the earlier return of working ability, and the economic savings to the patient and the hospital

Peritoneal Tap—Kaufman and his associates say that their interest in peritoneal tap was stimulated when they began an exhaustive study of perforation of peptic ulcers in an effort to reach an early diagnosis by administering methylene blue by mouth and recovering the dye by peritoneal puncture Peritoneal tap is performed with a number 18 or 19 gage needle $2\frac{1}{2}$ inches long through a small procaine hydrochloride wheal in the midline below the navel or to either side or in the epigastrium Peritoneal tap is a practical and safe procedure which requires extreme care in removal of the peritoneal contents and study of the smears and which affords evidence of the peritoneal reaction present by a simple and rapid laboratory study In children the procedure serves to differentiate streptococcal and pneumococcal peritonitis from appendicitis While a positive result of a tap is of diagnostic value, a negative result should be disregarded, especially in the face of other diagnostic signs, a negative result indicates usually only failure to obtain fluid which is present Peritoneal tap should be reserved for selected cases presenting confusion in diagnosis, and the interpretation of the smear must be painstaking In cases in which perforated peptic ulcer is suspected, when diagnostic data are confusing and likely to lead to exploratory laparotomy, the recovery by peritoneal tap of methylene blue previously introduced into the stomach will establish the exact diagnosis While the results of the procedure were of definite clinical value in only 14 of their 22 cases, the diagnosis in all of these presented great difficulties and could be established accurately only by exploratory laparotomy The tap in these cases established data that determined diagnosis and aided definitely in treatment as well as in evaluation of prognosis

Cavernous Hemangioma of Lung—Adams and his associates stress the rarity of hemangioma of the lung, pointing out that the case reported by them was the first in more than 240,000 admissions at the University of Chicago Clinics in the last fifteen years, and more than 4,380 necropsies at the same institution did not reveal another such lesion A man aged 24 entered the University Clinics complaining of frequent nosebleeds and colds over the last two or three years He also had suffered from generalized cyanosis and clubbing of the fingers and toes for at least sixteen years A roentgenogram of the chest revealed a large, irregularly shaped circumscribed opacity in the left lung and a small one in the right lung There were associated compensatory polycythaemia polycythemia and hyperhemoglobinemia After removal of the left lung the status of the blood approached the normal and the patient returned to work Most investigators who have reported cases similar to the 1 presented here have described the lesion as a cavernous hemangioma A careful study of the microscopic sections made from the specimen removed from their patient revealed only normal pulmonary tissue surrounding the three separate mesothelium lined cavities found in the left lung On the basis of the pathologic picture the lesions are really arteriovenous aneurysms or fistulas The pulmonary lesion produced a great compensatory change in the quality and the quantity of the blood Polycythemia (7200,000 cells) was present before operation with a corresponding increase in red cell mass (hematocrit reading 82 per cent) and hemoglobin (23 Gm per hundred cubic centimeters) The blood volume was approximately two times the

normal amount, the increase being entirely in the red cell mass After the removal of the left lung, all of the blood was diverted to the right side and was aerated as it passed through the right lung The red cell count fell more than 2,000,000 within two days and has remained at a high normal level The hemoglobin content was reduced from a preoperative level of 23.0 Gm to the present level of 15.7 Gm per hundred cubic centimeters The hematocrit reading was likewise reduced from 82 to 54 per cent The estimated total blood volume fell from 12,750 cc (preoperative) to 6,900 cc by the second postoperative day, this reduction being entirely in the erythrocytes Ten days later the blood volume was 6,350 cc, a value which is approximately normal Although only 4 similar cases have been previously reported, the condition in others has probably gone undiagnosed and been treated as polycythemia vera When clubbing of the fingers and the toes is present, some pulmonary lesion should be suspected and a roentgen examination of the lungs made A correct diagnosis may be readily established on the basis of altered values of blood oxygen and the finding of an opacity in the lung on roentgen examination

Fluorescent Factor F⁺ in Human Urine—Najjar and Wood described in 1940 the presence in urine of a substance with a characteristic bluish fluorescence the excretion of which was related to the availability of nicotinic acid, being increased in proportion to the nicotinic acid intake This substance, designated as F⁺, was regularly absent from the urine of patients with pellagra In this paper Najjar and his associates show that the highly fluorescent compound F⁺ obtained on treating urinary eluates with alkali and butanol is apparently derived from a precursor which shows only a slight bluish fluorescence The procedure used—alkalization and butanol extraction—serves to convert this precursor into the highly fluorescent compound F⁺ The identity of the urinary precursor is not yet completely established The highly fluorescent substance F⁺, formed from the urinary precursor, appears to be a butyl ether of N-methyl nicotinamide alcohacbinol

Pellagra Developing in Hospital Patients Receiving Vitamin B Complex—Roberts and Najjar report the history of a girl aged 12 Between August 1942 and April 1943 the patient's weight decreased from 78 pounds (35 Kg) to 60 pounds (27 Kg) The most conspicuous symptom during this period was anorexia Although offered a liberal diet containing cereal, eggs, bacon, green vegetables, meat, potatoes and a quart of milk daily, only small amounts of the quantity offered were taken The patient was frequently nauseated and at times vomited after meals Following admission to the hospital in April 1943 the patient continued a downward course Therapy consisted in a high caloric diet supplemented with orange juice and a liquid extract of yeast, given in doses of 4 cc per day, to furnish the B complex The hemoglobin fell to 8 Gm but responded well to a transfusion In spite of the supportive measures the patient continued to lose weight gradually Eight weeks after admission it was noticed that a symmetrical brown pigmentation had developed on the backs of the hands extending up to the knuckles, where it was sharply demarcated from the pale skin beyond Brown pigmented areas were likewise noted over the calluses of the elbows The suspicion of pellagra was borne out by the tongue, which was red, notably at the margins, and showed atrophy of the papillae The diagnosis was confirmed by studies of the excretion of the fluorescent

factor F₂ (N-methyl nicotinamide derivative) in the urine. Some light on the pathogenesis of the pellagra was obtained from a consideration of the vitamin content of the yeast extract which had been used in treating the patient. It was found that the daily dose which the patient had been getting contained 0.3 mg. of thiamine and 10 mg. of riboflavin but only insignificant amounts of nicotinic acid. The authors suggest that an obscure intestinal disorder, perhaps of the nature of a regional ileitis, interfered with intestinal absorption to an extent sufficient to cause pellagra. It is pointed out that certain commercial yeast extracts do not supply sufficient quantities of nicotinic acid.

Jaundice Following Administration of Human Serum.

—Oliphant shows that jaundice following administration of materials containing serum of the homologous species has been observed repeatedly both in man and in the lower animals. It is still unknown whether this type of jaundice is identical with naturally occurring so-called infectious hepatitis. The author presents the results of a sample survey of an epidemic of jaundice occurring subsequent to vaccination against yellow fever in the Virgin Islands in 1942. Jaundice was produced experimentally (1) by the inoculation of two lots of yellow fever vaccine containing human serum, (2) by the inoculation of small amounts of filtered serum from each of 3 persons and of a serum pool from 9 persons all of whom had previously received yellow fever vaccine containing human serum and (3) by inoculation of serum from 1 person who had early spontaneously occurring jaundice. Two serums which were interogenic when inoculated subcutaneously failed to produce jaundice by the intranasal route. Persons of all four Moss blood groups and both Rh positive and Rh negative persons were found to be susceptible. Susceptible persons did not give uniform local skin reactions to interogenic serums. The jaundice producing agent is filtrable and survives drying in vacuum, storage for long periods in serum at 4 C. and heating to 56 C. for one-half hour in the dried state. The agent was found to be present in the blood during the prejaundice period but not two and one-half months after the disappearance of jaundice. The interogenic agent is apparently inactivated by short exposure to ultraviolet irradiation. Transmission of jaundice by ordinary contact apparently did not occur during this experiment. Attempts to produce jaundice in experimental animals were unsuccessful. Antigens prepared from human livers and from chick embryos failed to fix complement in the presence of serums obtained after recovery from jaundice.

Penicillin in Sulfonamide Resistant Gonorrhea.—

Murphy treated 306 cases of sulfonamide resistant gonorrhea with penicillin. Of this number 262 cases were cured following the first trial on penicillin. Thirty-four failures following the first treatment were treated again according to another schedule, with recovery in all but 3. These 3 were treated again and now responded. The treatment consisted of a total of 100,000 units given over a twelve hour period in five doses of 20,000 units.

The foremost clinical observation was the persistence of urethritis following treatment. The character of the discharge changed from a purulent to a thin watery one. The mucous membrane of the urethra remained inflamed, glistening and moist beyond the time of disappearance of the watery discharge. In the majority of cases it was about one week after treatment before all evidence of the infection disappeared. In spite of the persistence of discharge and inflammation, all subjective symptoms such as dysuria, polyuria, hematuria and nocturia usually had subsided by the time the last treatment had been administered. The urine, after becoming clear, retained shreds in the majority of cases throughout the entire follow-up period. Only 1 patient had a generalized urticaria five days following treatment, which persisted for three days. Gonorrheal conjunctivitis is cured by the intramuscular administration of penicillin. Acute suppurative prostatitis responds slowly but favorably. Four cases of gonorrheal arthritis with concomitant gonorrheal urethritis showed no benefit from penicillin and in every case following the cure of the urethritis other treatments for the arthritis were required.

Corneal Vascularization and Riboflavin.—McCreary and his associates report studies to determine whether or not a slit lamp examination and the photographic procedure give comparable data and to throw further light on the effect of riboflavin on corneal vascularization and symptoms of eye fatigue. The results obtained from photographing the corneoseal junction with the ophthalmic camera and by an examination with a slit lamp are not significantly different. A study to demonstrate the effect of riboflavin on corneal vascularization has been carried out, using both photography and the slit lamp examination. The subjects studied were 41 students in the photographic division of the Canadian Air Force who had been provided with a ration containing when served 2.9 mg. of riboflavin per day for a period of one year. Approximately one half of the subjects were given a supplement of 3.3 mg. of riboflavin three times a day for two months and the others received placebos. There was no consistent change in corneal vascularization in either the treated subjects or the controls. The instillation of a simple irritant in the conjunctival sac caused collapsed, afunctional blood vessels in the cornea, transitional zone and conjunctiva to become engorged. As far as this study shows, it seems that a uniform peripheral corneal vascularization is not a safe basis for a diagnosis of riboflavin deficiency existing at the time of examination. Such a lesion may be due to riboflavin deficiency, but the deficiency could have occurred at any time previous to the examination. Also these blood vessels could have been reactivated by some cause other than lack of riboflavin.

Closed Plaster Method in Prevention of Shock.—According to Sellers and Goranson mortality from shock was greatly reduced when plastering was carried out immediately after the burn. They report a series of experiments designed to show whether any benefit in this respect can be derived from later application of plaster or from "pressure" dressings. It was found that immediate application of plaster bandages

decreases the mortality rate and hemoconcentration to a great degree. Some benefit in this respect accrues from application within one hour. Immediate application of plaster is more effective in decreasing the mortality rate from shock than is the immediate application of pressure dressings. As these experiments were performed with animals and under laboratory conditions, conclusions drawn from them should be accepted with reservations as to direct clinical application.

Thiouracil Treatment in Hyperthyroidism.—Astwood reviews observations on 62 persons who have been given repeated doses of thiouracil. Eleven had normal thyroids, while 51 had hyperthyroidism. Large nodular goiters were not common. Forty-one of the 51 cases were considered to be diffuse hyperplastic goiter with hyperthyroidism. In 8 of these iodine had been given shortly before thiouracil. The administration of 0.2 to 0.6 Gm. of thiouracil daily in two doses quickly controlled all the manifestations of hyperthyroidism in previously untreated cases. The metabolic response was slower in most cases of toxic nodular goiter, in iodine treated diffuse hyperplastic goiter with hyperthyroidism and in normal persons. A temporary enlargement and increased vascularity of the thyroid gland was noted in some cases. Exophthalmos usually improved slowly. Iodine still exhibited its characteristic effect on patients both during and after thiouracil therapy. Serious side-effects consisting of granulocytopenia and drug fever occurred in about 10 per cent of the cases during the early weeks of therapy. Adequate treatment, continued for longer than six months, was attended by a high incidence of lasting remissions.

Thiouracil in Thyrotoxic Patients.—McGavack and his associates observed 4 male and 22 female patients while under treatment with thiouracil. Fourteen of the patients were hospitalized, while the other 12 made no change in their usual routine of living. The patients were followed for periods ranging from six days to nine months. Characteristic effects in the adequately treated patient included a lowering of the basal metabolic rate, a decrease in pulse rate, a narrowing of the pulse pressure with diminution in the systolic figure, an increase in weight and an elevation of the value for total blood cholesterol. The size of the thyroid was moderately decreased under treatment with thiouracil, and creatinuria was diminished. No variations in blood chlorides, sodium or potassium were observed. Tests of liver function failed to show abnormality before or during treatment. A table lists the incidence of toxic reactions in 109 cases in which thiouracil had been given which had been previously reported by others and in the 26 here presented. In the total of 135 cases studied to date there were 16 (11.5 per cent) that exhibited a toxic or hypersensitivity reaction. Two of the 26 patients had severe toxic reactions. One developed agranulocytosis, the other a fever and widespread urticarial rash. The authors think that results of therapy with thiouracil have been sufficiently promising to warrant its extended and prolonged use in cases of toxic hyperplasia with a view to avoiding opera-

tive procedure. However, in this connection the toxic action must ever be kept in mind, and the clinician must be prepared to change his course when faced with early signs of unfavorable reaction.

Fibrinogen Coagulum in Removal of Renal Calculi.

Dees describes a new aid in the removal of small free stones from the renal pelvis at open operation. By the simultaneous injection of solutions of fibrinogen and thrombin, a strong coagulum which completely fills the pelvis and enmeshes all free stones is produced. On withdrawing this coagulum through the usual pyelotomy incision, all free stones should be removed. Fragmentation of calculi and trauma to the kidney are thus avoided. This operative procedure has been carried out on 21 patients without demonstrable ill effect.

Fibrinogen and Thrombin in Surface Treatment of Burns.

Hawn and his associates point out that, when large quantities of purified human fibrinogen and thrombin became available through the fractionation of human plasma to prepare albumin for the armed forces, studies were undertaken to develop from these proteins, which constitute important components in the natural mechanism for the protection of wounds, a dressing which would meet the specifications for an agent for the surface therapy of burns. They present observations on surgically denuded areas of animals and burns on human beings which suggest that human fibrinogen and thrombin mixtures have no deleterious effect on normal processes of repair. The use of preformed fibrin films prepared from the proteins involved in the natural coagulation mechanism is described in a small series of second and third degree burns. Such films are susceptible of adaptation to many programs of surface therapy. It is suggested that such films, particularly in the form of roll bandages, might prove a highly expedient fibrinogen-thrombin dressing for burns in the field, owing to simplicity and speed from the standpoint of application and to lack of bulk from the standpoint of transportation.

Clinical Use of Phthalylsulfathiazole.—Poth and Ross say that an extensive study covering twenty acylated sulfonamides in an attempt to find substances possessing antibacterial properties and being poorly absorbed from the alimentary tract has resulted in the synthesis and discovery of several compounds fulfilling these specifications. They report experiences with phthalylsulfathiazole, a condensation product of sulfathiazole and phthalic anhydride. It is an antibacterial agent of considerable interest and of therapeutic possibilities when activity restricted to the alimentary tract is desired. Approximately 5 per cent of the orally administered therapeutic dose is excreted in the urine. Ordinarily the concentration of the drug in the blood does not exceed 1.5 mg. per hundred cubic centimeters. As compared to their respective bacteriostatic activities, when measured by their ability to suppress the coliform organisms, phthalylsulfathiazole possesses roughly twice the activity of succinylsulfathiazole. In the absence of diarrhea and ulcerated lesions in the bowel a single daily dose of phthalylsulfathiazole will effectively lower the coliform organisms in the feces. The vegetative forms of *Clostridia* are greatly reduced following the oral administration of phthalylsulfathiazole, and stools are rendered odorless without ordinarily producing a diarrhea. The drug is likewise an effective bacteriostatic agent locally in the bowel, as is indicated by the alteration of the coliform bacteria in the presence of a watery diarrhea. An extensive study of absorption and excretion has shown that an average of 5 per cent of the oral therapeutic dose of phthalylsulfathiazole is excreted in the urine. Analyses of stools reveal that the content of phthalylsulfathiazole and a "free" diazotizable degradation product chemically similar to sulfathiazole varies between wide limits and that this "free" compound may maintain a concentration of 1,250 mg. per hundred grams. The authors describe preliminary trials of phthalylsulfathiazole in nonspecific diarrheas, bacillary dysentery, chronic ulcerative colitis and for the preoperative preparation of the large bowel. The drug appears particularly well tolerated by patients having ulcerative colitis and is quite effective in inducing and maintaining prolonged remissions. Severe toxic manifestations have not been encountered in patients with ulcerative colitis even though the therapy has continued for several months. Phthalylsulfathiazole can be maintained in high concentration in the diseased alimentary tract with low concentrations in the blood. It is suggested that the action of succinylsulfathiazole and phthalylsulfathiazole may not be due either wholly or in part to the formation of sulfathiazole by simple hydrolysis. As indicated by the alteration of the coliform flora in the bowel of man, phthalylsulfathiazole in half the dosage is as effective as succinylsulfathiazole.

Monocytic Leukemia with Oral Manifestations.—A man aged 66, who was hospitalized with the complaint of "sore mouth," had been treated by his dentist and physician for Vincent's infection since the onset of the oral symptoms, eight weeks previously, but there had been no improvement. Over the gingival tissues and in the mucobuccal fold were several large ulcers that were extremely tender to palpation. Their periphery was irregular, with marginal inflammation. Examination of the neck revealed a lymphadenopathy of the submaxillary and superficial cervical glands. There was also bilateral inguinal lymph adenopathy. The liver and spleen were enlarged a full hand's breadth below the costal margin. Over the trunk and extending onto the legs were painless areas of elevation and induration surrounded by hemorrhage. The blood picture showed a red blood cell count of 2,100,000 and hemoglobin of 51 per cent. The white blood cell count was 102,000 with the cells predominantly immature monocytes. The diagnosis was (1) acute monocytic leukemia, (2) leukemia cutis, (3) secondary anemia, (4) ulcerative leukemic stomatitis. The patient died a few days later. Aseltine stresses that progressive weight loss, persistent oral ulceration, malaise, pallor and skin lesions, any one or a combination of these, should arouse suspicion of a blood dyscrasia. Patients with blood dyscrasias exhibit decreased or little resistance against infection following the removal of teeth, and local necrosis results. The leukocytes are immature and unable to combat infective organisms, and so surgical intervention is definitely contraindicated.

Pneumonia, Pneumothorax and Emphysema Following Ingestion of Kerosene.—Scott reports the clinical history of a boy aged 2 who was admitted to the hospital two hours after he had ingested from 1 to 2 ounces of kerosene. Before bringing him to the hospital his parents gave him some cream, which caused him to vomit. Because of his apparent pulmonary edema he was given an immediate continuous infusion of 500 cc. of 20 per cent glucose followed by 10 per cent glucose in distilled water. In addition he was given oxygen continuously and caffeine with sodium benzoate. A saline enema followed by a rectal tube was used to relieve the abdominal distention. No gastric lavage was performed. Within two hours the child was conscious. The next morning his temperature had risen to 103.2 F., but he was alert and a bland diet was taken well. In view of the rise in temperature with an elevated white blood cell count, it was thought advisable to administer sulfathiazole.

His temperature became normal three days after admission and remained so until discharge. The roentgenograms revealed aspiration pneumonia, bilateral pneumothorax with possible bronchopleural fistula on the right, and soft tissue emphysema. Treatment was symptomatic except for the sulfathiazole medication. On the seventh day a roentgenogram revealed that the left pneumothorax was clearing. Both lungs had become more homogeneous. The heart was almost in the midline and the soft tissue emphysema was less severe. The patient made an excellent convalescence. Pulmonary manifestations following the accidental ingestion of kerosene are common in young children, but this is probably the first case reported with complications such as pneumonia, pneumothorax and emphysema.

Lyophil Human Serum in Pertussis.—Scheinblum and Bullova report observations on 23 patients who were selected for treatment because they were considered critically ill with pertussis as judged by their age, the severity of the attacks of paroxysms, apnea, cyanosis and emesis and the presence of pneumonic complications. The dried serum, the equivalent of 20 cc. of whole hyperimmune pertussis serum, was dissolved in 10 cc. of sterile distilled water and thus was concentrated by 50 per cent. Serum was administered intramuscularly to 22 patients; 17 of these patients received three 20 cc. doses, 4 received four 20 cc. doses and 1 received a single 20 cc. dose. Another patient received one 40 cc. dose intravenously, as suggested by McGuinness and his associates. The response of the young infants was apparently better than that of the older children. This may have been due to the fact that the age and weight of the patient were not considered in the dosage given. Sixteen of the 23 patients treated were under 1 year of age. None of these infants died. The 2 children who died were in the 1 to 2 year age group and were moribund when treatment was begun. Treatment early in the course of pertussis was effective. Two patients treated in the eighth and ninth weeks of illness had a good response. There were demonstrable circulating agglutinins following the administration of the serum. Lymphocytosis was suppressed after the administration of the serum. Eleven patients who had pneumonic involvement were treated with the serum in addition to sulfadiazine. There was no extension or recurrence of the pulmonary involvement and no development of pneumonia after a full course of serum therapy.

Thymectomy in Myasthenia Gravis.—Blalock reports the results obtained in 20 patients with myasthenia gravis on whom total thymectomy was performed. The duration of illness varied from seven months to twelve years. Four of the patients had had partial remissions. The preoperative neostigmine requirements ranged from 75 to 910 mg. daily. Only 2 of the patients had a thymic tumor. Most of the others presented a persistent two lobed thymus which on microscopic examination showed lymphoid hyperplasia with germinal center formation. Four of the patients have died since operation, three of the deaths occurring in the early postoperative period. Of the 16 remaining patients 3 are well, 5 are considerably improved, 5 are moderately improved and 3 have shown little if any improvement. The early and sustained improvement which has been shown by some of the patients makes it difficult to escape the conclusion that thymectomy was at least partly instrumental in causing the alteration. Unfortunately there is no known method by which one may predict the degree of improvement which may be expected to follow the operation. The results in these cases suggest that the best chances of recovery are to be expected with patients who have not had the disease for an extended period. The 4 patients who no longer require neostigmine had had myasthenia gravis for a year or less.

Agenesis of the Lung.—Valle and Graham present the histories of 2 living patients with agenesis of the lung. One case, that of a white woman aged 41, was proved by an exploratory thoracotomy after a clinical diagnosis was made of massive atelectasis of the left lung due to complete block of the left main bronchus. The other case, that of a white boy aged 5 years, is presumed to be agenesis of the lung since the physical examination showed asymmetry of the chest, absence of breath sounds and flatness to percussion on the left side. Also the x-ray film showed complete opacity on the left with displacement of the trachea toward that side, and the bronchogram showed a complete block of the left main bronchus. A bronchoscopy was performed which confirmed these findings. Review of cases from the literature indicates that absence of a lung is not incompatible with life nor does it preclude a long life. This fact is not surprising in view of what is well known now about the postoperative course of a patient after pneumonectomy. Of the 39 cases collected from the literature 25 were of children under 12 years of age. Eleven patients lived to be more than 19 years of age and 3 were 58, 65 and 72 years, respectively. Both of the authors' patients are living and are in fairly good health at the time of this communication.

Recurrent Urticaria Resulting from Contact with Browntail Moth.—According to Steele and Sawyer the browntail moth (*Nygmia phaeorrhoea*) reappeared in great numbers in central Maine during the summers of 1940, 1941 and 1942 with a corresponding increase in the number of cases of dermatitis traceable to contact with it. The caterpillars of this insect feed chiefly on foliage of the apple and related species but may also be found on oak, willow and other common hardwood trees and shrubs. The caterpillars cause both serious poisoning to many human beings and severe economic losses through defoliation of orchards, shade trees and woodlots. In the case reported an unusually high degree of skin sensitivity was shown to the poisonous products of the browntail moth larvae. Poisonous material from the browntail moth caterpillars, from the adult moth or from the nests, when it came in contact with the man's skin produced an immediate severe generalized urticarial response. A test dose of an extract of poisonous material produced a skin reaction. Injections were given at five day intervals through the various dilutions until the maximal dose of the most concentrated solution had been given. Soon after

injections were begun the patient reported that the urticaria was decreasing. He continued to break out locally when exposed, but a generalized eruption did not appear. Two months after completion of the desensitization treatment he reported that he had obtained good symptomatic relief and that the urticaria had practically disappeared. The authors believe that even better results might be obtained if it was possible to make up the desensitization extract from the full grown larvae or from barbed hairs obtained from such caterpillars.

Treatment of Cerebrospinal Fever with Penicillin.—Of the 31 cases of cerebrospinal fever constituting the basis of this report by Rosenberg and Arling 22 were proved to be meningococcal in origin. In the remaining 9 patients the clinical picture and findings in the spinal fluid were characteristic of meningococcal meningitis, but the stained smears as well as cultures of the spinal fluid and blood did not reveal organisms. Whereas the majority of patients in this series recovered following only one or two intrathecal injections of penicillin (10,000 to 20,000 Oxford units) in the more severe forms of meningitis larger amounts were necessary. As little as 20,000 Oxford units given intravenously over a four hour period, together with one intrathecal injection of 10,000 Oxford units resulted in recovery in 2 instances. The amount of penicillin required by different patients will vary with the number, type and virulence of the organisms as well as with the immunologic reaction of the host and will be indicated by the clinical and bacteriologic responses. As the clinical picture presented by the patients with bacteremia was indistinguishable from that observed in many patients with negative blood cultures it is contended that penicillin should be administered both parenterally (intravenously or intramuscu-

larly) and intrathecally to all patients with cerebrospinal fever. It is of paramount importance to continue penicillin intrathecally until recovery is assured. Penicillin need be administered parenterally only during the first twenty-four to forty-eight hours of treatment or for shorter periods in the milder forms of infection.

One Day Treatment of Sulfonamide Resistant Acute Gonorrhea with Penicillin.—Page and Hemmoff report that 30 cases of sulfonamide fast acute gonorrhea became bacteriologically negative within twelve hours after treatment with penicillin was instituted. Two of the patients had had three courses of sulfathiazole, 11 two courses of sulfathiazole, while 17 had had one course. One hundred thousand units of penicillin was given in five divided intramuscular doses of 20,000 units each, at three hourly intervals, as a complete course of therapy. No toxic effects were noted, blood counts and urinalysis done at three, twelve, twenty-four and forty-eight hour intervals were normal, urethral smears and cultures taken at three hour intervals during the course of treatment became negative within a period of twelve hours.

Accidents of Pregnancy S A Cosgrove—p 283
Some Dangers of Venoclisis in Cardiovascular Disease R A Houston—p 292

Uses of Cutis (Derma) Graft Transplant.—The term "cutis graft" means skin from which a thin layer of epidermis has been removed with a skin graft razor. Cannaday suggests that the reason this material is not utilized more widely in this country is the misconception that it is likely to cause epidermoid cysts. There is no record of the development of epidermoid cyst following the use of cutis graft. The cutis graft is gradually infiltrated with and is replaced by connective tissue, so that finally the graft takes on the characteristics of the structure that it replaces. In a hernial repair it is converted into fibrous tissue that resembles aponeurotic tissue, and when used to replace tendon it is rapidly converted into tissue resembling tendon. When used in the reconstruction of joints like the hip and knee joints it takes on the characteristics of normal joint lining. Cutis graft tissue can be used anywhere that fascia lata or other aponeurotic tissue has been used in the past. The author and his associates in the Charleston General Hospital have made use of cutis grafts in a total of 72 cases. The list includes several types of hernia, operations to suspend the uterine cervix for the relief of prolapse, wobbling knees, fractures of the patella, replacement of torn dura, support of the bowel in sigmoid colostomy and the like. Cutis may be used in all cases in which the use of fascia or tendon might be indicated with the expectation of better results. It heals rapidly and well, has great vitality, is able to survive under adverse conditions, possesses great tensile strength, has a good blood supply, gradually assumes the function of the part it replaces and is readily available. Its greatest value perhaps is in the repair of large incisional hernias.

Incidence of Rickets in Children Attending Hospitals in Bristol.—Corner describes investigations on the prevalence of rickets among infants under the age of 2 years who were attending hospitals in Bristol during the period from September 1938 to May 1941. Particular emphasis has been laid on the diagnosis of mild rickets during the first six months of the infant's life, as at that stage prophylactic measures would be most useful. Since the clinical diagnosis of rickets is apt to be uncertain in mild cases, the plasma phosphatase was estimated and correlated with the clinical evidence. X-rays were used in only a few cases, and serum phosphorus and calcium estimations were available in some cases. Microscopic examination of the ribs post mortem was carried out in a few cases. Evidence of rickets was searched for in 820 children in the age range of 2 weeks to 2 years. Rickets in which there were clinical signs and either x-ray evidence or an increase in the plasma phosphatase above 15 units was found in 31.4 per cent of the children. A further 3.9 per cent of patients may be considered to be early cases, since they showed no clinical evidence of rickets but the phosphatase was raised above 15 units. Some clinical signs suggestive of rickets were shown by 14.5 per cent of children, but other investigations were negative. There is a correlation between an increase in the plasma phosphatase and definite enlargement of the costochondral junctions, but when the enlargement is only slight the phosphatase is below 15 units in 81 per cent of cases, so that slight enlargement of costochondral junctions alone is not diagnostic of rickets. The incidence of rickets was greatest during the period six to nine months, when it was 52 per cent, and from twelve to eighteen months, when it was 48 per cent. Below the age of 6 months there were 26.2 per cent of definite cases. The incidence of rickets is 5 per cent lower in breast fed infants than in artificially fed infants. There is little difference in the incidence of rickets in infants who were fed on dried milks, milk mixture or sweetened condensed milk. The incidence of rickets in children who had received vitamin D supplement, which, however, often contained less than 400 units in the daily dose, was 10 per cent higher than in the other cases. The incidence of rickets did not show a definite relationship to rate of gain in weight except in the youngest group of infants. The incidence of rickets in twin and premature infants is not greater than the average for the whole age range, but in the youngest group of patients the incidence is doubled in the twin and premature infants. There appeared to be a definite relationship between the incidence of rickets and the type of antepartum diet of the mother. The incidence of rickets was greatest when the mother's diet was poor. Accessibility of direct sunlight and economic status of the family play a considerable part in the incidence of rickets.

Tuberculous Meningitis.—McMurray investigated two aspects of tuberculous meningitis: (1) the question why it does not arise in every case of tuberculous bacillema and (2) with what frequency the bovine type of tubercle bacillus occurs in tuberculous meningitis. Eleven patients with tuberculous meningitis were examined to determine the pathogenesis of the condition. It appeared that tuberculous meningitis commonly arises as the result of the extension into the subarachnoid space of a focus in the meninges or in the juxtameningeal tissues. This focus is blood borne and may or may not be one of the foci of miliary tuberculosis. Cerebrospinal fluids from 26 cases of tuberculous meningitis have been examined. Tubercle bacilli were found microscopically in 20 and strains have been isolated

in 24. Of the 24 strains isolated, 7 were of the bovine type and the other 17 of the human type. All the bovine strains occurred in the 20 children under 15 years of age. The source of infection with the bovine strains could not be established.

Dissection Lobectomy for Bronchiectasis.—Sellors and his collaborators point out that the dissection method of lobectomy has the advantages over the tourniquet method that the possibility of secondary hemorrhage is much diminished by individual ligation of artery and veins, the chances of fistula formation are diminished by careful closure of the bronchus, sepsis in the hilar stump is eliminated and the removal of the lobe can be said to be total rather than subtotal, which is the case in the tourniquet operation. A further problem in the evolution of the operation is the closure of the bronchus. When a reliable method of bronchial exclusion and the avoidance of fistula is discovered, lobectomy will have reached all the standards required of clean aseptic surgical technique. The 100 cases reviewed here were a consecutive series in which dissection lobectomy was done for suppurative bronchiectasis. The operative mortality was 6 per cent, and good results were obtained in 83 per cent. The most striking feature of the postoperative course has been the low incidence of pulmonary sepsis, and this is probably due to elimination of the hilar slough inevitable with tourniquet lobectomy. The incidence of postoperative atelectasis was high (29 per cent) but secondary pyogenic infection was exceptional. Pleural adhesions tend to lower the incidence of massive collapse, but their most important function is to expedite resolution of this condition. The commonest postoperative infection was tuberculosis, which developed in 7 cases, being fatal in 3. Pulmonary lobectomy by dissection is unquestionably a great advance on the tourniquet operation.

Influenza A Outbreak of October-December 1943.—According to Andrewes and Glover there occurred during the last quarter of 1943 in Britain the most widespread outbreak of influenza since the early months of 1937. Clinically the epidemic was mild. The small amount of influenza prevalent in the early months of 1943 was largely due to influenza virus B, but in April and in most of the summer months localized outbreaks occurred chiefly in service units, and serologic tests

(Hirst's technic) indicated that virus A was concerned. Hirst tests on serums obtained from patients who had respiratory infections between October and December yielded a high percentage of A positives. No rises in titer against influenza B virus was found. The strains isolated readily infected ferrets but were not easily adapted to mice. The serologic evidence indicates that at least 72 per cent—and perhaps 90 per cent—of the cases of influenza studied from October to December 1943 were due to influenza A virus. If the material available was a fair sample of that to be found in the country generally, this was a fairly pure A outbreak. Influenza virus B played no apparent part. Influenza of a similar type prevailed in the United States in the autumn of 1943 and also was predominantly of type A.

Rh Factor in Obstetrics.—Krieger reviews work on the Rh factor carried out at the Women's Hospital in Melbourne. Rh negative blood tests were made on the blood of all pregnant patients whose previous history had shown evidence of miscarriage or stillbirth. Four hundred and eighty-six such patients were tested between May and October 1943, and 101 (21 per cent) were found to have Rh negative blood. The author reviews the results of tests for Rh antibodies during and after delivery on mothers with Rh negative blood. With regard to the frequency of erythroblastotic children from mating of persons with Rh positive and Rh negative blood, the author finds that not all the babies of a mother with Rh negative blood and a father with Rh positive blood have Rh positive blood. Since the Rh factor is transmitted as a mendelian dominant, the fate of the children depends on the father's being homozygous or heterozygous for the factor. Furthermore, not every mother with Rh negative blood will produce isoantibodies to the Rh factor, and the amount of antibodies formed in any one pregnancy varies considerably. The mildest form of erythroblastosis, the hemolytic anemia of the newborn, may not be diagnosed as such unless attention has been directed to the possibility of its presence. Mild forms of erythroblastotic icterus may be classified as a rather severe ordinary icterus neonatorum if no special investigations are made. Although nothing can be done to prevent the action of Rh substance from the baby from producing Rh antibodies in the mother, or the passage of these antibodies through the placenta into the fetal circulation, the testing for the Rh factor and for Rh antibodies is necessary for several reasons, for instance, for proper blood selection, should either mother or child require a transfusion. The Rh factor should be investigated not only in women whose past history suggests the occurrence of erythroblastosis but in all women attending antepartum clinics at maternity hospitals. The question of the production of sufficient suitable typing serum is all important. Many difficulties are experienced in obtaining blood from the patients, even when a high titered serum has been detected. There is the fact that the titer of antibodies usually decreases rapidly. This necessitates the taking of blood from the patient within a week or two after her confinement. The patient or her doctor may object to this. There is also the question of variability of titer and "polyvalence" in serum from these patients.

*Nonconvulsive Electric Treatment in Depression P. Plattner and H. Löhms —p. 209
Juxtamedullary Dermoid Cyst L. Bakay, L. Benedek and A. Juba —p. 222.

Nonconvulsive Electric Treatment in Depression.—According to Plattner and Lohms it has been generally accepted that convulsions in the form of epileptic attacks are indispensable for the success of electric and other shock treatments and therefore the aim has always been to avoid incomplete attacks. The unpleasant complications such as wrenching of muscles and fractures were accepted as inevitable or attempts were made to minimize them by posture. Others, particularly American investigators, studied the possibility of reducing the convulsions by the use of curare or magnesium sulfate. The authors also unsuccessfully tried the use of magnesium sulfate but then decided to try weaker currents to avoid convulsions completely. They produced "absences" (temporary suppression of mental function) by passing a current of 60 volts for 0.1 second. The patient loses consciousness for only a few seconds and often is unaware that treatment has been given. More than 50 patients who on the average passed through 20 absences never experienced unpleasant sensations. A number of illustrative cases are reported. The authors conclude that for combating the depressive syndrome by electric irritation of the brain the elicitation of motor manifestations is superfluous and that the essential factor is that other, probably sympathetic, centers are stimulated. The convulsive manifestations may be undesirable secondary effects. It was found that arteriosclerotic and senile depressions can be effectively treated by the use of weaker currents that are tolerated even by old and fragile patients. Stronger currents are necessary in climacteric, involutional and endogenous depressions and such currents may produce convulsions and epileptic attacks, but to avoid the risk of fractures phenobarbital can be given, which does not interfere with the therapeutic effect of the electric current.

1:831-926 (Feb.) 1944 Partial Index

*Three Tests for Differential Diagnosis of Jaundice Lola Moyano Lopez —p. 855

Traumatic Rupture of Spleen H. F. Day —p. 885

Three Tests for Differential Diagnosis of Jaundice.—Moyano López performed tests of total blood bilirubinemia, phosphatemia and the Hanger test on 321 patients with jaundice. She concludes that the blood bilirubin test is of greatest value in recognizing parenchymal involvement of the liver. The blood phosphatase test is sensitive and reliable in the diagnosis of bile tract obstruction. Hanger's test is of moderate value in the diagnosis of alterations of the liver parenchyma. The average normal value of blood phosphatase in adults varies from 15 to 4 Bodansky units. Lower figures indicate a bad prognosis. Blood phosphatase is slightly increased in the course of hepatitis. It may reach an average value of 10 Bodansky units. A lowering of blood phosphatases approaching normal values in the course of hepatitis together with a lowering of the figures of blood bilirubin and a decrease of the Hanger test indicates a favorable course of the disease. A sudden acute increase of blood bilirubin to very high values after a drop to 50 or 90 mg. of bilirubin per thousand cubic centimeters of blood together with unchanged results of the blood phosphatases and Hanger's tests indicate a fatal prognosis. If blood bilirubin reaches high figures and then drops to 80 or 90 mg. and remains at these levels while the blood phosphatase increases beyond 10 Bodansky units and the Hanger test increases, the case is one of hepatitis complicated by bile tract obstruction. In a case of jaundice, if blood phosphatase is slightly above 10 Bodansky units, blood bilirubin about 200 to 300 mg. per thousand cubic centimeters and Hanger's test is faintly positive, jaundice is due to an old obstruction which has affected the liver in such a way as to lead to hepatitis.

Book Notices

The Pathogenesis of Tuberculosis. By Arnold R. Rich, M.D., Associate Professor of Pathology, The Johns Hopkins University School of Medicine, Baltimore. Cloth. Price, \$10.50. Pp. 1,008, with 90 illustrations. Springfield, Illinois & Baltimore: Charles C Thomas, 1944.

This timely book by Rich, well qualified by training and experience to present the subject of pathogenesis of tuberculosis, is written clearly and in orderly style. It incorporates the basic factors and principles which influence the occurrence of tuberculous infection or determine its progression or arrest. An analysis within the present limits of our knowledge up to 1940, about the time the bibliography ends, considers the influence of each of those factors on the pathogenesis of the disease. This compilation of the literature brings into a unified whole the basic and interdependent but scattered and isolated facts contributed by bacteriology, immunology, pathology, clinical observation, experimental investigation, epidemiology and genetics. The book is broader than previous treatises on tuberculosis alone and includes an analysis of the basic principles that govern infection and resistance in general. Whenever a stand is taken, it is based on the first hand examination of original papers, to which there are 1,417 references, or from the author's personal experiences. In the author's words in the preface, "Those who deal with the manifold problems of tuberculosis in their work or teaching are faced continually with the need of a survey," such as this book presents. The author has endeavored to present the principles of native and acquired resistance and hypersensitivity, as far as they are understood at present, in a manner that will enable those who are not specialists in immunology to understand them readily.

Without becoming too critical, it is hoped that the author will not be content to let this issue stagnate before revamping it at regular intervals for new editions and will seek the advice of others qualified in this field. The shortcomings of single authors for extensive volumes should be recognized. However, full credit should be given Rich for the stupendous task he has performed in preparing a volume on the pathogenesis of tuberculosis the equal of which has never before appeared in English. His subject is driven methodically toward a goal beginning with the relations of the chemical constituents of the bacillus to pathogenesis, in which he displays chemical capability. The types of bacilli, variations in form and potentialities are well defined. Under virulence he points out that the study of the bacilli from human sources is not adequately fulfilled nor can we regard different forms of spontaneous disease as being specifically determined by the degree of virulence of the infecting bacilli. Native resistance is elaborately considered in four complete chapters to the conclusion of its mechanism. Following local tissue resistance, hypersensitivity and its mechanism are dwelt on, leading into the problem of specific and nonspecific desensitization; this chapter will require radical modification in new editions because of the uncertain status of this phase of tuberculosis prior to 1940. The mechanism of acquired resistance is fully detailed and climaxed by a good chapter on the factors that influence resistance. The influence of the number of bacilli impresses one with how a simple phase of tuberculosis still requires elucidation. Finally the problems responsible for the characteristics of tuberculous lesions and symptoms, exogenous or endogenous reinfection and the application of the principles of pathogenesis as illustrated by tuberculosis of the lungs, meninges and serous cavities complete the picture of tuberculosis sufficiently to conclude with the decline in the mortality and the future outlook, which becomes the expression of the author as to the importance of each of the major factors. Rich does not appear to contribute to the view that tuberculosis will be self extinguished with the mortality curve trend. He feels that "the disease that still kills more than twice as many individuals as any other single cause of death during this (15 to 44 years of age) particularly productive and enjoyable period of life span can hardly be jubilantly regarded as being nearly conquered." To the latter view most tuberculologists and investigators will certainly contribute at present. Such a view also attests the need for this volume, and it is doubtful whether any single author could have done a better job with

so complex a problem as the pathogenesis of tuberculosis and all its implications than Rich did.

The volume is well composed and is worth possessing. It will help students and medical men to a better understanding of tuberculosis.

Simplified Diabetic Management. By Joseph T. Beardswood Jr., A.B., M.D., F.A.C.P., Associate Professor of Medicine, Graduate School of Medicine, University of Pennsylvania, Philadelphia, and Herbert T. Kelly, M.D., F.A.C.P., Associate in Medicine, Graduate School of Medicine, University of Pennsylvania. Fourth edition. Cloth. Price, \$1.50. Pp. 172, with 9 illustrations. Philadelphia, London & Montreal: J. B. Lippincott Company, 1944.

As a manual for the diabetic patient, this volume covers the ground thoroughly and in a manner both concise and clear. The present edition is somewhat revised, notably by the addition of a section on the newer insulin preparations with prolonged action. The inclusion of crystalline insulin among the latter is a rather surprising lapse in an otherwise accurate presentation. The authors present two systems of diet calculation, the unit method and the percentage method. Both are clearly and simply explained and accompanied by the appropriate tables of food values. However, it is apparent that the authors have abandoned their earlier use of the *diet prescription chart based on the "line-ration schemes"* of Lawrence and of Christian and O'Hara. In view of this it is rather strange that, although all reference to it has been removed from the text, the chart is still included in the volume and is still featured in the blurb on the dust cover.

Conferências do curso de aperfeiçoamento de psiquiatria de guerra (organizado pelo Prof. A. G. Pacheco e Silva sob os auspícios da Faculdade de medicina da Universidade de S. Paulo e dos fundos universitários de pesquisas para a defesa nacional). Paper. Price, Cr. \$50.00. Pp. 301, with 11 illustrations. São Paulo, 1943.

The volume presents the twenty-two lectures given during 1943 in a postgraduate course on war psychiatry organized by Dr. Pacheco e Silva, professor of psychiatry in the University of São Paulo. Dr. Pacheco e Silva and fifteen of his colleagues have embodied a thorough study of the various applications of psychiatry to the problems of war; considering first the general scheme of examinations, they proceed to the various clinical pictures as met in a military setting, then to such problems as malingering, laws and regulations, and mental hygiene, individual and collective. The volume is substantial evidence of the foresight and progressive scholarship of our psychiatric colleagues in Brazil.

The Woods Hole Marine Biological Laboratory. By Frank R. Lillie. Cloth. Price, \$4. Pp. 234, with 28 illustrations. Chicago: University of Chicago Press; London: Cambridge University Press, 1944.

The Woods Hole Marine Biological Laboratory is a unique institution located on the south shore of Cape Cod on a spit of land between Buzzards Bay on the one side and Vineyard Sound on the other. It is a research and collecting institute joined by strong ties to departments of zoology in many of the country's leading universities. Its importance to medicine lies in its fundamental contribution to an allied science and in the not inconsiderable number of physicians who have received early biologic training in this laboratory. Professor Lillie has been closely connected with the laboratory since its earliest days, and it is both fortunate and appropriate that he should be the author of this welcome history of its scientific and economic development.

Leukopenia and Agranulocytosis. By William Dameshek, M.D., Clinical Professor of Medicine, Tufts College Medical School, Boston. Edited by Henry A. Chrislian, A.M., M.D., LL.D., Clinical Professor of Medicine, Tufts College Medical School. [Reprinted from Oxford Loose-Leaf Medicine with the Same Page Numbers as in That Work.] Cloth. Price, \$1.75. Pp. 841-852. New York, London & Toronto: Oxford University Press, 1944.

This monograph summarizes the present knowledge of conditions in which the leukocyte count is decreased. The material is timely, for, as Dr. Christian says in the preface, "interest in leukopenia and agranulocytosis has been increased markedly in the present period because not infrequently both appear as toxic manifestations of the therapeutic use of sulfonamide drugs." The subject matter is well arranged and presented, and the bibliography of 152 references is selected from the rather extensive literature on the subject. Of especial value are the sections on etiologic factors and on treatment.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

MORTALITY OF BREAST AND BOTTLE FED INFANTS

To the Editor:—Can you give me information on the proportion of women who can nurse their babies? Most physicians now seem to advise bottle feeding as at least equally desirable. What is the comparative mortality of breast and bottle fed babies?

Mobel D. Murphy, M.D., Glendale, Calif.

ANSWER.—Sanford (Various Complementary Feedings Used During the Neonatal Period, *THE JOURNAL*, Aug. 5, 1939, p. 470) in a study of 4,622 infants during the newborn period found that 14 per cent of the mothers were unable to nurse their babies, 30 per cent required some complementary feeding and 56 per cent were able to give their babies sufficient breast milk by the end of the tenth day of life. Statistics on the mortality of breast and bottle fed babies are open to criticism unless they represent the same group and environment and are large enough and cover a long enough period of time to make a fair comparison. In the Infant Welfare Society of Chicago from 1924 to 1929 in 20,000 babies under 1 year of age in which 91.5 per cent were completely or partially breast fed and 8.5 per cent artificially fed, the mortality was 11 per thousand. Of this mortality 66 per cent were artificially fed, 27.2 per cent partially breast fed and 6.7 per cent completely breast fed. In the same organization in 1943, 6,702 babies under 1 year of age were cared for with approximately the same proportion of feeding. The mortality has now dropped to 4 per thousand, but still of this mortality 65 per cent were artificially fed, 28 per cent partially breast fed and 7 per cent breast fed.

DIFFERENTIAL DIAGNOSIS OF APICAL OPACITIES

To the Editor:—A soldier aged 23 was hospitalized four months ago and carefully studied because of the presence of infiltrative lesions of both lung apices. Diagnosis of atypical pneumonia was finally made. The patient has now been asymptomatic for about three months. He states that he feels well, and his general appearance is that of a person in good health. However there is no x-ray evidence that the lesions are either regressing or progressing. Other data are negative. Would this man be qualified for full duty or light duty or should he be hospitalized until the lung lesions have disappeared?

Lieutenant, M. C., A. U. S.

ANSWER.—What led to the discovery and careful study of the abnormal shadows in the lungs? Were they discovered during and after an acute sickness resembling virus pneumonia? If the soldier actually had a form of virus pneumonia the residual changes in the lungs are probably of no importance and he would be qualified for full duty. Residual shadows are common after virus pneumonia because of the interstitial location of the lesions. Nevertheless, it is unusual for changes to persist so long and in both apices. Under the circumstances mentioned, unless the acute attack was observed, it is not safe to make a diagnosis of virus pneumonia in retrospect simply because of the changes recorded, as apparently was done. The abnormality may have been present for a long time before. The roentgenogram made at the time of induction should be reviewed for comparison.

Pulmonary tuberculosis is a strong possibility as the cause of the apical densities, and the case should probably be regarded as such until proved otherwise. Further appropriate investigation along this line is advised. Virus pneumonia and pulmonary tuberculosis are sometimes difficult to differentiate, as recently discussed by Yaskalka (*Am. Rev. Tuberc.* 49:408 [May] 1944). The management of a suspected case of tuberculosis is fully covered in Army Medical Regulations.

GAUZE SPONGE IN ABDOMINAL SURGERY

To the Editor:—Please give an opinion on the use of the small dry gauze sponge in the abdominal cavity. If intestines are held and they slip, will such a sponge cause adhesions?

J. Louis Woldner, M.D., Loveland, Colo.

ANSWER.—It is not possible to predict whether or not in any given case adhesions will form following an operation. Traumatizing the peritoneum favors formation of adhesions. If the intestine is to be held for any length of time, it would be preferable to use a wet sponge rather than a dry gauze sponge as suggested in the query.

HOMOSEXUALITY AND ENDOCRINE IMBALANCE

To the Editor:—At one of our clinical conferences we discussed the subject of homosexuality. It was the opinion of one of the medical officers that recent work has shown an excess of estrogen in the blood, spinal fluid and urine in a large number of homosexuals of both overt and latent types. This was disputed by another medical officer, who claims that recent work at Hartford, Baltimore and Philadelphia has failed to show any such findings. In view of the fact that our medical references are inadequate, I take this opportunity to ask the following questions: 1. What is the latest concept concerning the estrogen content in (a) homosexuals, overt type, and (b) homosexuals, latent type? 2. What is the latest work done on this subject, where was it done, and what are the findings? 3. Is the treatment of homosexuals purely a psychiatric problem, an endocrine problem or both? 4. What percentage of homosexuals do show endocrine imbalance, and what type imbalance is it?

M.D., Washington.

ANSWER.—Surprisingly little quantitative laboratory work has been reported in the study of homosexuality from an endocrine point of view. The most recent publication is by Abraham Myerson and Rudolph Neustadt (Bisexuality and Male Homosexuality: Their Biologic and Medical Aspects, *Clinics* 1:932 [Dec.] 1942). This article provides, in addition to discussion, an adequate bibliography of the other recent work. These authors agree fundamentally with the conclusions of C. A. Wright (*M. Record* 154:60 [July 16] 1941) that the commonest pattern in the urinary excretion of male homosexuals is a relative increase in estrogenic substance and decrease in androgenic substance. This is not always an absolute increase or decrease from the normal pattern. Myerson and Neustadt state that "it becomes necessary, in all candor, to point out certain serious shortcomings in the chemical studies of urine hormone: (1) Urine is an excretion and, therefore, cannot adequately measure endocrine activity; (2) the methods are imperfect and, for example, do not measure testosterone but only its breakdown products; (3) inert chemical substances, so far as sexual activity is concerned, participate in the color reactions, and so some falsification of the values occurs; (4) the patients do not live under standard experimental conditions. Nevertheless, and despite all these shortcomings, certain clinical facts are correlated to the urinary findings in definite ways, so that diagnostic facts of importance emerge."

It should be noted that the conclusions of Wright and his group have been vigorously challenged by A. C. Kinsey (Homosexuality: Criteria for a Hormonal Explanation of the Homosexual, *J. Clin. Endocrinol.* 1:424 [May] 1941). The objections raised are on the basis of inadequate grounds for statistical conclusions by the authors. Kinsey produces evidence of a frequent homosexual tendency among males who also have heterosexual interests and capacities but contributes no further information about the hormone picture.

It is manifestly too soon in the process of endocrine study of this field to answer the question about the percentage of homosexuals who show endocrine disturbance, let alone to decide how frequently homosexuality is an endocrine, how frequently a psychiatric, problem. Myerson and Neustadt feel that they see evidences of endocrine disturbance in 83 per cent of all cases of overt male homosexuality examined as compared to a similar endocrine disturbance in not more than 2.5 per cent of other cases studied. They are unable to come to any conclusion as to which is primary, the psychologic or the endocrine disturbance.

PSORIASIS

To the Editor:—For several years I have had moderate psoriasis; at times it is clear, and again it becomes severe. It is worse at present on the scalp and the arms and legs. Exposure to sunlight, less effectively to ultraviolet radiation, daily, for thirty days practically eliminates the psoriasis. However, it is impossible for me to do that, being so busy. Have large doses of vitamin D, by mouth, given equivalent results to those obtained by daily exposure to sunshine? Would it be advisable to take the oily vitamin since most patients with psoriasis have a high cholesterol? Would the oil increase the cholesterol? The studies on lipocac which were demonstrated at the session of the American Medical Association in Cleveland were encouraging, but I have seen no reports on that since. Is lipocac available to the general practitioner as yet? What suggestions can be offered for the treatment of this stubborn disease?

M.D., Iowa.

ANSWER.—Cedar and Zon (Treatment of Psoriasis with Massive Doses of Crystalline Vitamin D and Irradiated Ergosterol, *Pub. Health Rep.* 52:1580 [Nov. 5] 1937) treated 15 patients with psoriasis, all between 30 and 50 years of age and all with old psoriasis resistant to treatment. They were given pure crystalline vitamin D in sesame oil, 50,000 units to the capsule containing 5 minims (0.3 cc.) of sesame oil, six capsules per day. These were taken between meals to avoid any augmentation of their action by milk products in the diet, as suggested by Lewis (*J. Pediat.* 8:308 [March] 1936). Of these patients 11 were cleared of lesions in from six to twelve weeks of treatment. The blood calcium was estimated at intervals and was

seen to increase slowly in all but 1 case. It reached 12 mg. per hundred cubic centimeters in some and up to 16 mg. per hundred cubic centimeters in others. Three untoward reactions were seen in the tenth to the twelfth week of treatment: anorexia, nausea and urinary frequency. These reactions occurred after the lesions of the skin had cleared, and they disappeared on cessation of treatment. Patients with calcified pulmonary tuberculosis, as evidenced by roentgen examination, were excluded from this group to avoid possibility of absorption of the protective calcium. Six patients had mild recurrences in from eight weeks to five months after treatment had been stopped. One of these responded to a second and again to a third course of treatment for eight to ten weeks. Four other cases had remained clear of lesions three to eight months after the end of the treatment.

Neither vitamin D nor lipocain can produce results to equal those of actinotherapy in the treatment of psoriasis. Most dermatologists get better results from the Goeckerman treatment than from any other one method. O'Leary (Goeckerman Method of Treating Psoriasis, *Canad. M. A. J.* 48:34 [Jan.] 1943) describes it in detail as practiced in the place of its origin. The ointment, consisting of

	Gm. or Cc.
Crude coal tar.....	2.0 to 4.0
Zinc oxide	2.0
Corn starch	50.0
Petrolatum to make.....	100.0

is applied thickly and a suit of cheap underwear is worn over it. Once a day the ointment is removed except for a thin film and the ultraviolet light given through this film, enough to cause a slight erythema. The dose is increased daily to maintain the erythema without causing blisters. Then the patient spends one-half to two hours in a bath at 95 F. After this the ointment is again applied. Every other day autohemotherapy is given, the series ending with the fifth treatment. On the scalp, in place of the coal tar ointment, one containing 5 per cent ammoniated mercury and salicylic acid is used. This course of treatment necessitates a stay in the hospital for two weeks. Most dermatologists find the hospital treatment hard to sell to their patients, who prefer a longer course of milder treatment compatible with continued work. Keini's modification calls for application of a 2 to 10 per cent crude coal tar in cetyl alcohol emulsion base before retiring, and in the morning a tar bath. At the doctor's office undiluted solution of coal tar is painted on each lesion before the ultraviolet treatment is given.

HARRIS DRIP PROCTOCYCLYSIS—"GAS PAINS"

To the Editor:—What is the present status of the Harris drip used post-operatively? Does it reduce distention? How much water is absorbed by this method in twenty-four hours? Does it produce peristalsis in the small intestine? If it does, is not this harmful in the presence of peritonitis? What are "gas pains"? Can you tell me when the original paper on this method was published? Frances B. Doyle, M.D., Brooklyn.

ANSWER.—The Harris drip, unlike the continuous drip proctoclysis first introduced by the late Dr. John B. Murphy, has never been adopted extensively by the profession, and many experienced surgeons and clinicians are unfamiliar with it. The available literature on this method is conspicuous by its extreme paucity. In the light of current methods of preoperative preparation and postoperative treatment its present status must be considered as obsolete in large measure. There are no available recorded observations on the influence of the Harris drip on distention, on the amount of water absorbed in a twenty-four hour period or on its influence on peristalsis in the small bowel. The late Joseph Blake of New York, in a discussion of the postoperative treatment of infective peritonitis (Nelson Loose Leaf Surgery 5, pp. 22-23), regarded the Harris method as superior at that time.

There appear to have been few authoritative experimental or clinical observations with respect to the factors underlying the production of "gas pains." Such gas pains have been attributed to a variety of causes, including preoperative or postoperative purging, the excessive use of opiates, the nature of the anesthetic, rough handling of tissues during operation, too early or too late feedings and the like. A conventional discussion of the subject is found in Cutting's Principles of Preoperative and Postoperative Treatment (New York, Paul B. Hoeber, Inc., 1932, pp. 311-342). However, Mendes-Ferreira's roentgenologic observations on human subjects (*Proc. Staff Meet., Mayo Clin.* 13:222 [April 6] 1938) greatly discount the importance of gas in the genesis of postoperative abdominal pains, so that the expression "gas pains" is in all probability a misnomer. No reference has been found to any published original paper on the Harris method.

INDUSTRIAL EXPOSURE TO MERCUROS CHLORIDE

To the Editor:—A problem has arisen in a drug manufacturing business. The main product is a venereal disease prophylactic. The women who fill the tubes and clip, wipe and pack them naturally get calomel ointment (33½ per cent) on their hands, but they are instructed to wash their hands well with soap and warm water, using a brush, at noontime and again before leaving for home in the evening. Until recently an employee has complained of mercurial poisoning. One employee, after six weeks of this work, was confined to bed for ten days, complaining of pains in various joints, especially the knees, ankles and spine; she also had diarrhea but no soreness of the gums. At the time of her illness she had just completed a course of eight injections, twice weekly, of synadal. Another employee about 45 years of age after three weeks' work complained of stiffness and pains in the joints, especially in the legs, but no soreness of the gums or diarrhea. I insisted that these 2 women were not suffering from mercurial poisoning because of the lack of typical symptoms of mercurial poisoning, their careful personal hygiene, the lack of abrasions on the hands, the shortness of time of employment, and the fact that there have been no other cases among many employees since 1921.

R. M. Nicholson, M.D., Los Angeles.

ANSWER.—The manifestations reported do not suggest mercury poisoning. Joint pains and diarrhea are sometimes present in mercury poisoning, but not as the most characteristic features. On the other hand, the absence of stomatitis and gingivitis by no means rules out mercury poisoning, since their absence is frequent. Mercurous chloride is so insoluble that neither mercury dermatitis nor systemic involvement often occurs. Trivial absorption through the skin may take place, but absorption from the lungs after inhalation of mercurous chloride dust has been denied. In pharmaceutical houses many thousands of man-days have been devoted to the manipulation of this substance without the causation of mercury poisoning. One large manufacturer reports that over a period of years not a single instance of either mercury dermatitis or systemic poisoning from mercurous chloride has appeared among the workers handling this substance.

Even after intramuscular injection of calomel, as in the treatment of syphilis, absorption is not certain. Andrews states that "the insoluble salts such as calomel are so slowly and irregularly absorbed that their use is attended by hazards of prolonged ineffectiveness due to failure of absorption or prolonged overdosage due to tardy absorption." Directly in contact with the skin, mercurous chloride infrequently causes skin pigmentation, which may be persistent.

It appears to be true that, when mercury poisoning arises from mercurous chloride, in most instances some fortuitous event has led to the transformation to the mercuric state. A wide variety of chemicals effect this change, but such chemicals are not likely to be on hand under the circumstances of the operations mentioned in this query. On a theoretical basis, long exposure of calomel to sunlight may change the state of calomel to mercury bichloride, as may also long continued elutriation.

In this instance mercury poisoning is regarded as improbable from the information furnished, but various steps might be utilized to eliminate uncertainty. Quantitative determination of mercury should be made on both urine and blood. However, such determinations do not represent simple laboratory tests. The quantity of mercury in the atmosphere, should atmospheric mercury be suspected, may be measured through the use of the General Electric mercury detector. Most important of all, thorough clinical examinations should be carried out, following the procedures indicated in United States Public Health Service Bulletin 263, published in 1941 and entitled "Mercurialism and Its Control in the Felt-Hat Industry."

ESTROGENIC HORMONE THERAPY AND CANCER

To the Editor:—Has it been proved that average of estrogenic substances might induce cancer? I have been using 1.5 cc. five times monthly of the 10,000 international units. Is this correct or "overuse"?

Laurel S. Sherman, M.D., Oakland, Calif.

ANSWER.—Estrogenic substances may induce cancer in animals. There are records of cases in man which suggest that tumor formation has followed estrogenic therapy. However, the true dangers have not been definitely outlined; they have merely been suggested, so that all who use estrogenic therapy should do so with caution. Regarding the prescribed dosage, it is difficult to say whether this represents "overuse" without knowing how long it has been continued and under what conditions. New and Nonofficial Remedies suggests a dosage for estrogenic substances of from 2,000 to 20,000 international units injected one or more times weekly, depending on the response of the patient. After relief has been produced, dosage should be lowered to a maintenance level. Dosage varies for other conditions, such as kraurosis vulvae and gonorrheal vaginitis in children.

THE RADIOLOGIC ASPECT OF THE UROLOGIC PROBLEM

CHAIRMAN'S ADDRESS

ROBERT A. ARENS, M.D.

Director, X-Ray Department, Michael Reese Hospital
CHICAGO

A decade and a half ago, intravenous or excretory urography was introduced by Swick¹ and von Lichtenberg,² who simultaneously published the results of their investigations with iopax (uroselectan) and its action with reference to the urinary tract in the *Klinische Wochenschrift* in November 1929. This work received confirmation from Heritage and Ward³ early in 1930 in England and was soon further confirmed in this country by a host of investigators. The value of the procedure was quickly recognized, and it was promptly adopted as a routine examination. The usual difficulty of obtaining an adequate source of supply of the necessary drug was rapidly overcome. From an initial dose, intravenously given, of 300 cc. administered by using six 50 cc. syringes or by buret, our chemical confrères shortly were able to develop a satisfactory solution so concentrated that it could be put up in 20 cc. sterile ampules, making the method available to the profession at large. The success of the method depended on the excretion of an iodine fast radical, with the urine, from the kidneys. This made it possible to outline the urinary tract, since the iodine radical gave a density to the excreted urine almost comparable to retrograde pyelographic mediums. At first the iodine content was not sufficient to cast entirely satisfactory shadows, but today, with intravenous solutions available with an iodine content of from 40 to 70 per cent. very satisfactory results are produced.

The method of making this examination is now too well known to warrant a detailed explanation. Let it suffice to say that it is simple and safe if a few precautions are observed. Our standard routine is to start with a scout film or a KUB film. The patient is thoroughly purged the evening before and the intravenous injection is made the following morning, without breakfast. We feel that purging is exceedingly important, for an intestinal tract full of food or feces can well interfere with proper visualization of even large calcific stones in the kidney, ureter or bladder. This was again impressed on us recently when a scout or

survey film, taken just prior to an intended examination, showed a large stone in the left ureter, but because of intestinal contents small stones in the lower calix of each kidney were not visualized. (This patient was not prepared.) Fortunately, since we make it a routine practice never to proceed beyond the scout film examination unless we feel that the entire urinary tract is satisfactorily visualized, these stones were revealed without difficulty in another KUB film after adequate preparation. After a satisfactory scout film has been obtained, our routine consists of roentgenograms made at five, fifteen and thirty minutes. We feel, however, that each case is a law unto itself, and therefore each film is checked, after development, and the routine changed accordingly, if necessary, with exposures made at varying intervals even up to twenty-four hours. Routine is maintained only in cases which are obviously normal.

The method is not without its difficulties and hazards. Severe reactions have been encountered after injection of the medium, with a few fatalities, patients who died apparently as a direct result of the intravenous injection. Pendergrass reported a series of twenty-six deaths out of approximately 661,800 cases, in addition to 11 previously reported. However, an analysis of his survey would indicate that only ten of these twenty-six deaths occurred directly as a result of the procedure. It is true that the other 16 patients had had an excretory urography done, but the statistics would indicate that they undoubtedly died from some other concurrent condition rather than that their deaths were due per se to the method. Pendergrass's figures show that in his series of cases, including the entire 26, only 0.0039 per cent showed a lethal reaction. If one can eliminate sixteen of the deaths classified as delayed, in which there is a question as to the cause of death being the intravenous medium, then the actual figures are exceedingly low, somewhere in the neighborhood of 0.0014 per cent, instead of 0.0039 per cent, as claimed. Other reactions are fairly common, such as flushing, nausea, urticaria, itching, venospasm, pain in the shoulder, sense of constriction in the pharynx, phlebitis and cerebral irritation. Hypersensitivity simulating anaphylactic shock may also be present. It appears, from the literature and from personal contact with radiologists, that the present methods of preexamination sensitivity tests, such as making an intradermal, mouth or conjunctival test, regardless of whether they are negative or positive, are not satisfactory criteria as to whether the patient will or will not react to the application of the drug. It is my understanding that the reactions which have occurred have been due more to extraneous material contained in the glass ampules than to the solutions per se, and this has now been rectified. I agree entirely with the suggestion of Pendergrass that in each room where the rographic study is to be made a tray should

be available containing epinephrine 1:1,000, atropine sulfate, caffeine with sodium benzoate and sterile hypodermic syringes for immediate use if necessary. It seems, however, that in the past several years, while reactions more or less severe have occurred, no lethal sequelae have been reported.

The method appears to be a safe one, barring unforeseen allergic or chemical reactions, which might apply to any medication or preparation given intravenously.

Due consideration must be given to contraindications, and extreme care must be employed in using contrast mediums for patients with "severe liver disorders, nephritis, exudative diathesis and severe uremia."⁴ Also the method should be used with caution for patients with pulmonary tuberculosis, hyperthyroidism or hypertension and for patients with a history of allergy.

The usefulness of excretory urography is immediately apparent when one considers the cases in which a study of the urinary tract is indicated but the passage of the cystoscope or of shadowgraph catheters is impossible, contraindicated or undesirable. The value of excretion urography was immediately realized. Here we had a method particularly adaptable in those cases in which we were dealing with pin point ureteral orifices, many times impossible to locate in the bladder, or, having passed a catheter, to meet suddenly an apparent ureteral obstruction, finding it impossible to pass the catheter up into the renal pelvis. Another group of cases which give the urologist difficulty in retrograde pyelography are those of ureteral stricture, a small urethral meatus, prostatic hypertrophy, severe bladder hemorrhage or fistula, in which ureteral catheterization is impossible or contraindicated. Without excretory urography it is almost impossible to determine the presence of certain genitourinary diseases or anomalies in young children and infants. While I feel today that bilateral simultaneous retrograde pyelography is a safe procedure, especially when using the same contrast medium that is injected intravenously, many urologists still hesitate to make this type of examination. Many radiologists still hesitate to make this type of examination and consequently fail to examine the opposite, apparently normal, kidney. It is good, sound practice to visualize the unsuspected kidney whenever possible, but to obtain information relative thereto necessitates a second catheterization, which is not always desirable. Excretory urography may supply this information. In woman, pressure on the bladder by an enlarged uterus due to fibroids, pregnancy or the like, or pressure from altered pelvic adnexa, makes it difficult or impossible to pass a shadowgraph catheter, and here again excretory urography may prove to be a very satisfactory method of determining the status of the urinary tract.

Those conditions which have been well shown in a characteristic manner by excretory urography include the positive findings of pyonephrosis, hydronephrosis, ureteropelvic kinks with obstruction, due to aberrant vessels or adhesions at the ureteropelvic junction, with obstruction anywhere in the ureter, renal tuberculosis, polycystic kidney, traumatic kidney, congenital absence of a kidney, ectopic kidney, neoplasm, horseshoe kidney, double renal pelves, double ureters, radiolucent calculi in either the kidney, ureter or bladder, ureteral polyp,

hypernephroma, anomalies, carcinoma of the bladder or tuberculosis of the bladder. Excretory urography, however, is not entirely a substitute for retrograde catheterization with pyelography, but there are many occasions on which it elicits certain information obtainable in no other way. Many cases in which cystoscopy and the passage of shadowgraph catheters are contraindicated can be easily handled by the new method, and information can be gleaned that would otherwise be impossible to secure. On the other hand, intravenous pyelography alone is often sufficient and, in addition, gives a good idea of renal function.

An important diagnostic factor, not commonly considered, is the differential diagnosis of shadows in the right upper quadrant, especially between gallstones and renal calculi. These stones often simulate one another in their structure and density. When this occurs, proper rotation films following excretory urography may differentiate one from the other. If there is a gallstone present, it is invariably possible to rotate this shadow entirely out of and away from the kidney contour, thereby definitely ruling it out as a renal calculus.

It is of the utmost importance that the radiologist and the urologist collaborate to the fullest possible degree to obtain the best results from excretory urography. It is only by close team work between the two that the best interests of the patient are conserved, and the closer the liaison the more the value of the procedure. The radiologist should have at his command the history and the laboratory findings and, in the light of these latter, many times he may suggest additional films, under different conditions, the nature of which he has learned through his appreciation of the reaction of normal renal anatomic and gross pathologic conditions of the urinary system, when subjected to the influences of opaque mediums.

SUMMARY

It may be of value to call attention to a few fundamental maxims of urinary tract examination which it might be well to bear in mind:

1. Proper and adequate preparation of the gastrointestinal tract is an essential prerequisite to satisfactory roentgenograms of the urinary tract.
2. An ideal roentgenogram of the urinary tract is one which shows the detail, including the kidney outlines.
3. The kidneys are too often obscured by material in the gastrointestinal tract, which may be so dense as completely to vitiate stone shadows.
4. Failure to visualize a urinary calculus (KUB films) does not signify that a stone may not be present. There are radiolucent calculi that cast no shadow.
5. Even a large calcific ureteral stone may not register a shadow on the film when it lies over the ala of the sacrum. Even large calculi in this location have been missed.
6. A scout film of the urinary tract is usually only the first step in a proper x-ray examination.
7. There is no controversy between excretory urography and retrograde pyelography. Either one or the other, with a scout film, or all three combined, may be necessary before a satisfactory result can be obtained.
8. It is as important to visualize the normal renal pelvis as the pelvis of the suspected kidney.

4. Pendergrass, E. P., Chamberlain, G. W., Godfrey, E. W., and Burdick, E. D. A Survey of Deaths and Unfavorable Sequelae Following the Administration of Contrast Media. *Am J Roentgenol* 48:754 (Dec.) 1942

9. The use of modern intravenous pyelographic mediums for bilateral simultaneous retrograde pyelography has made the procedure a safe one.

10. A suspect stone shadow, apparently in contact with a shadowgraph catheter, may prove to be outside the ureter or kidney, when rotation films are made.

11. Do not judge stone shadows in the right upper quadrant and within the kidney outline too hastily. They may prove to be gallstones.

12. Lack of excretion (excretory urography) from one kidney does not necessarily mean a "dead kidney." A small stone in the ureter may produce a calculus anuria, even though the stone may not be visualized. It has been noted that renal function has been restored within five minutes after a ureteral calculus has been passed into the bladder.

With reasonable precaution excretory urography, in experienced and competent hands, is a safe and valuable procedure, and one which frequently gives information obtainable in no other way.

2839 Ellis Avenue.

THE MEDICAL DIRECTION OF HUMAN DRIVES IN WAR AND PEACE

MAJOR GENERAL DAVID N. W. GRANT

The Air Surgeon

WASHINGTON, D. C.

The greatest challenge which faces the medical profession today, in my opinion, is the physical and psychologic rehabilitation of the returning war veteran as a member of his community.

Three years ago the medical profession was called on to mobilize its ranks for service in the armed forces. We did so. How well we met that challenge is being demonstrated in the high quality of medical service we are delivering every day on every front. This was a second challenge—the performance of our mission as doctors at war—and we shall continue to accept it and concentrate our energies on war medicine until the last wound is healed.

In the Army Air Forces, however, we have accepted rehabilitation, psychologic as well as physical, as a function of war medicine. Our Convalescent Training Program has proved that this task should begin as soon as the soldier is hospitalized and should continue without interruption until he is able, and knows he is able, to resume a useful life as a soldier or a civilian. Our success in this direction, which places the primary responsibility for rehabilitation within the military organization, has demonstrated that the over-all problem of human reconversion—the task of converting soldiers back to citizens—is not waiting an end of war. They are returning in thousands from the beachheads of Salerno, Anzio, Tarawa, Normandy and Saipan and from the airdromes of England, Italy, Burma and the Pacific. For many of these sick and wounded the war is already over. This current situation may be regarded as a pilot run on the immense rehabilitation project to come when millions of war veterans are restored to civilian environment.

By this I do not mean that millions will be disabled. The physically handicapped will be numerous, too

numerous, unfortunately. The job of physical restoration and mental readjustment of the physically disabled is clearcut. It is being tackled in an organized and effective manner by the Army, the Navy, the Veterans Administration, the American Medical Association and the many civilian and government agencies associated in the Baruch Committee on Physical Medicine.

THE PROBLEM OF REHABILITATION

My point is that, in comparison to those with outright disabilities, a far greater proportion of our returning war veterans will be able bodied but psychologically different from the civilians who left their communities to enter military service two, three or four years before. They have different attitudes, different feelings, different emotions, different drives, and they present a problem of rehabilitation which is complicated and obscure. The nature of their problem is difficult to understand and complex in its solution. While these differences in behavior fall within the field of psychiatry, they do not apply merely to the neuropsychiatric casualty—the case of frank war neurosis, or operational fatigue, as it is known in the AAF. More specifically, I am speaking of the war veteran who would be classed as normal by any ordinary physical or mental standard but whose attitudes and drives have been altered by the impact of war.

From the time he was inducted, this man's foremost desire has been to get home again. He carries it through the rigors of training and the terrors of battle. He is nonetheless loyal and he fights nonetheless well because of his human yearning to go home. But when he goes, when he is again among his relatives and his friends in his home town, he may be engulfed with the feeling that everything is changed, that he somehow has been cheated. He feels disappointed, disillusioned, depressed and dissatisfied. He may be tense and restless and even wish he was back in combat. His lost feeling may express itself in an attitude of resentment and hostility toward the people and the community he loves. He may come to feel more like a victim of these people than their hero.

What has happened to this man is not hard to understand. It has received some public attention, but the story needs to be made a part of a national educational campaign. Such a program must start with the elimination of the widespread misunderstanding which exists in the mind of some physicians as well as the general public as to the significance of terms like "psycho-neurosis" and "neuropsychiatric casualty" and as to the nature of military psychiatry. In the first place, for most of us physicians the methods of psychiatry seem mysterious, esoteric and incomprehensible. Where other medical specialists may see and palpate the hernia by physical examination, find a kidney stone or an ulcer by reading an x-ray film or identify typhoid by a bacteriologic test, the psychiatrist can diagnose a functional disturbance of the central nervous system only by a qualitative analysis of changes in the patient's behavior and personality. While to most of us this interpretation of illness from actions and reactions seems an intangible way of making a medical diagnosis, you will see, if you think about it, that it is a social practice in which we indulge every day. Constantly we are judging one another by the deviations of the subject's conduct from the conventional. We reach glib conclusions that Joe is "a crazy guy" or Jack "acts funny."

But we accept them and maybe even admire them. We excuse the man who has a spell of being crabby, jittery, seclusive, bellicose or eccentric as being somehow different than usual and let it go at that. But if Joe or Jack goes to a psychiatrist we may change our minds, because psychiatrists are commonly identified with the treatment of the mentally disordered and unbalanced, and we think that any one who needs a psychiatrist must be pretty badly off. All of us, of course, have an instinctive distrust and aversion for the insane. Actually, the psychiatrist probably agrees with us that Joe or Jack "acts funny," but he calls it a psychoneurosis or functional nervous disorder, which to him doesn't even imply a psychosis or insanity. But the damage is done because the person is in the hands of a psychiatrist, and Joe or Jack is tagged with a name which the American public has come to think of in terms of weakness.

This impression makes it difficult for the public to believe that soldiers who have been labeled as "NP"—or neuropsychiatric—are no different from other people who get the jitters or become upset in difficult and harassing situations. By any working standard these men were accepted as normal in their communities, which is the environment to which they usually are best adapted. Even those who were rejected for military service at the outset on neuropsychiatric grounds tend to fall within normal standards as far as their civilian environment was concerned. In it they were capable of making good social and occupational adjustments, but in a military environment of discipline, regimentation, insecurity and hardship they did not look like good fits. Outside of the comparatively small group of soldiers who were psychoneurotic or less frequently psychotic but were able to get by the induction examination, the war psychiatrist is dealing with a normal person in an abnormal environment.

This is the message that the physician, the relatives, the friends, the employer and the community of the war veteran should hear. Whether he is labeled a neuropsychiatric casualty or is discharged for some other reason or is merely home on leave, any differences in his behavior probably comprise a hangover from his normal reactions to an abnormal way of living—and dying.

What war has done is to call on this individual to accept the abnormal idea that self preservation is less important than self sacrifice—that there is a distinction between killing a man in peacetime and killing him in war. Conditioned throughout his formative years to seek security and comfort, to love peace and freedom, the raw recruit is quickly and brutally exposed to a system which, first in training and then in combat, subordinates his personal security to that of the group, continually replaces comfort with hardship and strain, offers him peace only as the distant reward for making war, and denies that freedom is preferable to authoritarian discipline and regulation.

It is difficult for the individual to adapt himself to this military deflation of his ego, to this superimposition of the group ego on, and frequently against, his will. All men are alike in that they have feelings and in that these feelings may run into emotional conflict with other feelings which are equally acceptable. In our fliers we have observed a number of basic conflicts. The most obvious is that of the fear of destruction conflicting with the compulsion to fight. The individual's instinct says flee, but the will of the group says fight. There

is the very real conflict between one's sense of duty, or patriotism, and one's worries over one's wife and child. There is the conflict in the desire to stick by your friends in the squadron when your ego tells you to "save yourself." And there are conflicts arising from a feeling that your friend in the ball turret or in the wing position was killed because of some personal failing on your part. One of the most interesting conflicts observed in our fliers has nothing to do with the man's peacetime conditioning but with his complete acceptance of flight as a normal environment. He loves to fly. He is the "natural," and you will hear him say "Doc, I'd rather fly than eat." He means it. The airplane gives him a lift spiritually as well as aerodynamically. To get up there in the sky and look down on the earth inspires in him a sense of majestic freedom, a kinship with the gods. But a conflict arises from his discovery that, as the result of combat flying, the thing he loves seems bent on destroying him.

Can these soldiers who have faced tensions and stresses far beyond any peacetime demand on their organism be regarded as mentally suspect because they carry the anxieties they have developed in combat back home with them? You know the answer is no. They have reacted normally to an essentially inhuman environment and in most cases have made remarkably good adjustments to their military environment up to a point where no man could be expected to endure much more. They are not failures because they may have developed certain symptoms of anxiety. Each man has his individual tolerance point for military stress. The basic soldier, uprooted from the local environment and transplanted in the training camp, may not be able to make the adjustment. The flier, who has made every adjustment from the original load imposed on him in the aviation cadet center throughout the two years it takes him to complete his flight training, in a few instances may not be able to make the final adjustment to combat flying.

But the great majority of them do, and they fly their missions, twenty-five, fifty or more, carrying their anxieties into battle and out again. They are the strong and the successful. But when they have completed their tour of duty and returned to the United States, they bring their differences in behavior with them.

These men have been poured into a mold, the mold of war, and to remove them from it requires adjustments as profound as those they were forced to make when they changed from civilian to military environment. They present all degrees of difficulty in adjusting to the peaceful, prosaic and trivial circumstances of home life after learning to live in a fighting group which so orders their life that it can give all or take all with one word from one commander. One man, flexible, resilient, may come home, take his wife on a fishing trip and settle down to being "good old Bill" again without so much as a harsh word. Things are different, but he can "sweat" anything out. Another highstrung race horse of a man perhaps finds that the releases he found in combat are boiling over in hostility toward his mother's solicitation or in a desire to punch the nose of every civilian he sees on the street.

There will be every gradation in the changes which war has wrought in the behavior of these men, because of the differences in their drives, their conditioning, their physiology and their attitudes. Any man forced to conform to an environment in which he does not fit well develops nervous tension and therefore psycho-

neurotic symptoms. The greater the incompatibility between his personality and the environmental stresses, the greater the tension and the more severe his symptoms. The longer the stresses are continued, the more worn out he becomes from the tension.

The individual's personality can be described as having the characteristics of the curved leaf in a spring, such as found in an automobile. If the spring is forced to conform to a curve either greater or less than that to which it was molded, the spring is under tension. The greater the discrepancy from the natural curve, the greater the tension, and the more the steel is fatigued.

Like the various leaves in the spring, each individual has his own curve and will have to be bent in varying amounts to fit in the curve of tension imposed by combat. If the tension has been sufficient to fatigue his personality, he may be slow to spring back to the shape in which his original environment molded him.

This is the challenge we face each time a war veteran returns home—to see that he has full opportunity to spring back to his original personality curve. Given a little time and a little help, most of them will. The original curve of that spring is strong, and removal of abnormal stress and tension is curative in most cases. But the changes from an environment of tension to one of relaxation is a radical one and, in instances in which the fatigue of the personality has been great, special help must be given in making the adjustment.

What we are dealing with is the problem of fitting individuals into groups—individuals who express themselves in some sort of work—groups designed to produce in some fairly specific manner. Perhaps at first glance this does not seem like a medical problem. In the experience of the Army Air Forces it is. The AAF Medical Service has found a direct relationship between a man's health and the group to which he is assigned. If he is not doing the right job or the group is not doing its job, he tends to become unhappy and inefficient, and these characteristics may be manifested in various breakdowns in his health. If after breaking down he is not reoriented as a member of a productive group his recovery is slow and perhaps incomplete.

COMBAT FLYING

In dealing with the highly specialized occupation of combat flying, we have developed a program in aviation medicine which I feel introduces a new concept in medical practice or at least brings previously unrelated branches of science into a medical focus.

Our first interest in the flier is the matter of selection. Each candidate must have the physical capacity. The medical examination for flying performed by the flight surgeon emphasizes not only general mental and physical fitness but also normal function in vision, hearing, equilibrium and personality. Each man must also have the psychologic aptitude for learning to fly. Our aviation psychologists have developed the most comprehensive mass psychologic testing program in history—all for the purpose of fitting the individual into the occupational group where he has the greatest chance of succeeding. This wartime demonstration indicates that an entire industry or even an entire nation could make progress by determining an individual's physical capacity and psychologic aptitudes and then training him for the task for which he is best fitted.

Our second interest in the flier is the preservation of his physical and psychologic fitness to fly. A flight surgeon is assigned to each squadron. The flight surgeon, through his participation in the working environment of his patients, occupies a position which is rather unique in medicine, although it has some precedent both in the country doctor, who was a power in his community, and in the industrial surgeon, who is interested in occupational diseases and hazards. One of the flight surgeon's main interests is the prevention of operational fatigue, the occupational disease of the flier. The syndrome of operational fatigue, made up of a composite of emotional and fatigue symptoms, is a product of chronic tension and physical tiredness manifesting itself in a state of anxiety. It is a destroyer of individual efficiency and laterally group morale. Any contribution to morale aids in the prevention of operational fatigue, and nothing contributes more to morale than good leadership. The fitness of the individual for his job depends on physical capacity and psychologic aptitude, but the fitness of a group of fit individuals depends more than anything else on the intelligence manifested by the leadership in directing the group toward the logical utilization of its abilities. It has been one of the most profound observations of the war, I think, that not only the efficiency but also the health of a group is affected by the quality of leadership. Medical officers have observed both in the Air Corps and in the Infantry that weak leadership is reflected in a high neuropsychiatric casualty rate and strong leadership in a low rate. Thus you see that treating the sick individual is secondary to the function of treating the healthy group so that its members will not become sick.

Our final interest in the flier is the restoration of his physical capacity and psychologic aptitude for productive work after he has become sick. This is the function of the AAF Convalescent Training Program. We operate five convalescent hospitals where the flier returning from combat with a physical disability or with operational fatigue may be given the special attention needed for his rehabilitation. The first objective is to salvage him for further military service for he, after all, is the man who was a success and not a failure in his military occupation. If it is not possible to rehabilitate him for resumption of flying duty, an attempt is made to retrain him for ground duty. Only as a last resort is he discharged back to civilian life. If this is necessary, every effort is made to prepare him for this change of environment.

Convalescent training is fourfold in its approach. It aims at physical reconditioning, psychiatric restoration, vocational reorientation and resocialization. If it's a job the man is worrying about, we help him find a job to his liking. If he has a family problem, we try to work it out with his wife. In fact, because of the husband-wife problems rising out of changes in the patient's behavior we have established orientation courses for wives of returning war veterans.

As an example of what can be done if the group makes an effort to rehabilitate its own members, I will cite results obtained at one of our convalescent hospitals in a series of cases of severe operational fatigue. By severe I mean that these individuals returned from successful completion of their combat tours with such symptoms as restlessness, tension, tremor, overactivity of the sympathetic nervous sys-

tem, psychosomatic disturbances, anxiety states, phobias, depression, guilt reactions, inability to concentrate, mental confusion, weight loss, insomnia, battle dreams, irritability, startle reactions, loss of appetite or aggressive impulses. All were in need of psychiatric treatment in addition to rest, physical reconditioning and general reorientation. The results among officer flying personnel was restoration of 61 per cent to full flying duty, 8 per cent to limited flying duty and 27 per cent to ground duty. This made a total of 96 per cent rehabilitated in military service. Owing to less incentive, the full flying duty restorations among the enlisted flying personnel were much lower: 28 per cent. An additional 6 per cent were restored to limited flying duty and 48 per cent sent back to ground duty, making a total of 82 per cent rehabilitated in military service.

In considering these results it should be noted that in a psychiatric case the individual's desires are an important factor in deciding whether he should fly again or not. The fact that two thirds of the flying officers and one third of the enlisted men who had suffered severely from the stresses of their combat environment are willing to go back is significant of the potentialities of a medical approach based on the relation of the individual's capacities and aptitudes to the occupational group. After all, these men had made their sacrifice, and it might be expected that none of them would care to return to an environment which had caused them distress. I believe that a great many of our fliers, once the end of the war has relieved them from the abnormal tensions of combat, will realize that they are completely conditioned to a flying environment. They will then be normal men in normal environments.

REDIRECTION OF ENERGIES FROM WAR TO PEACE

As for the rest, we have directed the drives of these war veterans into winning a war and now face the responsibility of redirecting their energies into peace. You may feel that this war veteran is the problem of somebody else—of the psychiatrist, the psychologist, the sociologist. He is, indeed, their problem, but he is everybody's problem—the problem of his government, his community, his employer, his relatives, his friends and his doctor. No one should be better qualified by reason of scientific training and humanitarian interest than the physician to give direction to a national program which will redirect the drives of these men into socially constructive, individually satisfying channels.

The medical profession, I am convinced, has a profound opportunity stemming from the task of reorienting these men in their group. This is the development of a new type of preventive medicine seeking to improve the individual's health and efficiency by his orientation in an intelligently directed group in which he has the aptitude and desire to work. In this field, which we may for the moment call industrial community medicine, lies the challenge of transplanting to the soil of civilian industry some of the constructive discoveries we have made in the prosecution of a technological war.

In reality, the family doctor now becomes the specialist, and strangely enough his specialty has already been defined in medical terminology. He is a specialist in orthergasia, which literally means the conditioning of man to normal function and adjustment.

Headquarters, Army Air Forces.

PENICILLIN IN OPHTHALMOLOGY

LIEUTENANT COLONEL JOHN E. L. KEYES
MEDICAL CORPS, ARMY OF THE UNITED STATES

After the accidental discovery by Fleming¹ in 1929 of the inhibitive effect of penicillium mold on staphylococci in vitro, no effort was made to apply this knowledge in a clinical way until the studies begun by Howard W. Florey and his co-workers in 1940. Since then the organic acid formed by *Penicillium notatum* and named penicillin has been extensively investigated.

Observations on the use of penicillin in the treatment of ocular diseases in man have been published by Abraham,² the Floreys,³ Keefer,⁴ Mary Florey,⁵ Keyes,⁶ Sorsby,⁷ Lyons,⁸ Griffey⁹ and Cashell.¹⁰

Material for this communication was derived from the special penicillin research center at Bushnell General Hospital, from private communications of medical officers of the Army and from medical literature on penicillin. No effort was made to compile statistics by treating a number of similar cases with penicillin. Research, which was essentially clinical, was directed toward establishing the sphere of usefulness of penicillin as an ophthalmic drug. The information presented in this report is tentative and subject to modification as our knowledge of penicillin increases.

More than 20 bacteria clinically sensitive to penicillin have been described. The following penicillin sensitive pathogens are encountered in ocular diseases: *Streptococcus alpha*, *beta* and *gamma*, *Staphylococcus aureus* and *albus*, *Neisseria gonorrhoeae*, *Neisseria intracellularis meningitidis*, *Neisseria catarrhalis*, *Pneumococcus*, *Corynebacterium diphtheriae (mitis)*, *Clostridium welchi*, *Actinomyces bovis*, *Treponema pallidum* and diphtheroids. Grouped according to penicillin sensitivity, the most highly sensitive organisms are the (beta) hemolytic streptococci, gonococci and some strains of staphylococci. *Streptococcus viridans (alpha)*, *Streptococcus anhemolyticus (gamma)* and the remaining organisms named are less sensitive. *Staphylococci* vary from extreme sensitivity to extreme resistance. Resistant strains are frequently found in skin and superficial wounds. Coagulase positive staphylococci are presumed pathogenic.

It has been observed by Walker¹¹ in mixed infections, in which organisms resistant to penicillin are

present with organisms sensitive to penicillin, that the destruction of the sensitive bacteria by penicillin aided in the healing process if the sensitive bacteria were virulent pathogens. If the resistant bacteria were responsible for the virulence of the infection, penicillin therapy was less beneficial.

APPRAISAL OF PENICILLIN

Great care has to be exercised in appraising the efficacy of penicillin in a given ocular infection. The unavoidable error of clinical observation is high. Many ocular diseases are self limiting. Any therapeutic agent employed in such a disease may be credited erroneously with expediting recovery or causing a cure. Two illustrative cases are described:

A case of acute bilateral conjunctivitis secondary to nonhemolytic *Staphylococcus albus* and Koch-Weeks bacillus was treated by instillations of penicillin 1,000 units per cubic centimeter in one eye and 3 per cent solution of sodium sulfathiazole in the second eye. Negative cultures and a clinical cure were obtained in seven days. The staphylococcus was sensitive to both drugs; the Koch-Weeks bacillus was resistant to both drugs. A second case of bilateral acute conjunctivitis secondary to hemolytic *Staphylococcus albus*, coagulase negative, was treated in a similar manner. Conjunctival cultures were negative in four days, and clinical recovery was achieved in nine days. The result in these 2 cases of acute conjunctivitis offered little choice between the use of penicillin and of sodium sulfathiazole. Both patients were hospitalized. Sodium sulfathiazole probably would have been the drug of choice in office practice.

Penicillin is the drug of choice in the treatment of gonorrheal ophthalmia. The Floreys³ had startling success with penicillin in a case of gonococcal ophthalmia neonatorum. "The gonococcal case of ophthalmia neonatorum had shown no response to three and a half weeks' sulfapyridine and irrigation. The discharge was profuse even under quarter hourly irrigations. Penicillin (1,200 units per cubic centimeter) was dropped into the eye hourly. In twelve hours the pus had much diminished and in two days it had gone; the eyes were open and the conjunctivae white. No gonococci were seen in films made eight days later, after penicillin had been discontinued for forty-eight hours. No recurrence was reported." Sorsby⁷ and his co-workers reported that they had cleared the conjunctiva in thirty-six hours with penicillin therapy of gonococcal ophthalmia neonatorum. Griffey⁹ successfully treated a man aged 24 suffering from sulfonamide resistant gonorrheal ophthalmia and gonorrheal urethritis of forty-six days' duration. "Therapy consisted of intramuscular injections of 25,000 units of penicillin sodium every three hours for a total of ten injections." Cultures of *Neisseria gonorrhoeae* were grown from the eyes and the urine. Similar cultures taken after five and one-half hours' treatment were negative for gonococci. Local therapy was confined to atropine as a mydriatic. Final vision was normal bilaterally.

These results contrast favorably with those reported by Sorsby and Hoffa.¹² They treated 60 cases of gonorrheal ophthalmia in children with sulfonamides and reported a clinical cure in three days in 51.7 per cent of

the cases and in eight days in 90 per cent of the cases. Sulfapyridine, sulfathiazole, sulfamezathine and sulfadiazine were given internally. These results were unusually good previous to the advent of penicillin therapy.

Penicillin should be given preference also in the treatment of streptococcal and sensitive staphylococcal infections. Some strains of staphylococci are resistant to penicillin. Cross infection is a frequent occurrence. If the new organism is not sensitive to penicillin and assumes virulence, the progress of penicillin therapy will be altered unfavorably. Walker¹¹ is of the opinion that loss of virulence under treatment by a strain of staphylococci resistant to penicillin is problematic. Several chronic orthopedic cases were treated for three different periods with rest intervals. The bacteria did not become penicillin fast. He encountered one organism that became resistant under treatment.

A case of resistant *Staphylococcus aureus* infection is reported briefly:

A soldier with chronic ulcerative blepharitis, subacute conjunctivitis and pyoderma of his face was found to have hemolytic *Staphylococcus aureus*, coagulase positive, in cultures from lesions of the conjunctivas, eyelids and face. A solution of sodium penicillin, 1,000 Oxford units per cubic centimeter of isotonic solution of sodium chloride, was instilled into both eyes every two hours for thirty days. During this period of treatment the right eye on one occasion and the left eye on two occasions, coincidental with a temporary increase in the facial infection, became acutely red and superficial marginal ulcers of the cornea developed. It was discovered that this strain of staphylococci was resistant to penicillin in concentrations of 10,000 units per cubic centimeter on a seeded nutrient agar plate. The organism was mildly sensitive to sodium sulfathiazole in 3 and 5 per cent solutions in vitro. The strength of the penicillin drops was increased to 10,000 Oxford units. The patient complained of considerable local irritation, and at the end of thirty-six hours withdrawal of the treatment was contemplated. The brand of penicillin was changed, and further treatment was well borne. Penicillin 10,000 units per cubic centimeter was continued every two hours for seven days. At this time conjunctival cultures from the right eye showed nine colonies of hemolytic *Staphylococcus aureus*, coagulase negative, and from the left eye diphtheroid organisms. Cultures from both eyes were sterile four days later. The blepharitis had disappeared. The lower palpebral conjunctiva was mildly congested. The facial pyoderma, which had not been treated, was quiescent. The patient was referred to a dermatologist for treatment of his skin.

One month previous to treatment of his blepharoconjunctivitis, this patient was treated with penicillin parenterally for a left mastoid infection, from which were cultured a beta hemolytic streptococcus and a nonhemolytic *Staphylococcus albus*.

The possibility of desensitization of the strain of staphylococci found in the eyelids and conjunctiva by previous penicillin therapy has to be considered, even though staphylococci were not demonstrated in the mastoid. The prolonged exposure of the nonsensitive pathogen to penicillin may have reduced its virulence, but remissions occur in this disease.

The treatment of meningococcal conjunctivitis with sulfonamide compounds, both locally and orally, has been favorably reported by Theodore and Kost.¹³ Eight patients with this disease so treated were clinically and bacteriologically cured in not more than

12. Sorsby, A., and Hoffa, Elizabeth L. The Sulfonamides in Ophthalmia Neonatorum, Brit. M. J. 1: 353 (March 11) 1944.

five days each. Local application of penicillin could not offer much improvement on this record. Penicillin administered parenterally is not secreted in the tears or cerebrospinal fluid; therefore this method of treatment would not be applicable.

The toxin of diphtheria is not neutralized by penicillin. Diphtheria antitoxin should be administered also in the treatment of diphtheritic conjunctivitis. Penicillin is an auxiliary to other known methods of treatment of gas gangrene. Walker¹² reported gratifying success in several cases of actinomycosis with parenteral administration of penicillin. Mahoney¹⁴ and Bloomfield¹⁵ have reported sensitivity of *Treponema pallidum* to penicillin. Riba¹⁶ confirmed their results with penicillin parenterally and intrathecally in cases of early syphilis and neurosyphilis. Diphtheroid organisms are seldom virulent. They are susceptible to local penicillin therapy.

ILLUSTRATIVE CASE REFERENCES

Ulcerative Keratitis.—Local and systemic penicillin therapy is indicated in acute, severe ulcerative keratitis in the presence of a sensitive organism. In chronic indolent corneal ulcerations, local penicillin therapy should be given a trial. Penicillin sometimes has a beneficial effect and hastens the termination of prolonged stubborn corneal ulcerations. Two illustrative cases are summarized briefly:

A white soldier aged 21 acquired an ulcerative keratitis of his left eye in March 1943 secondary to unidentified trauma. There was a diffuse central corneal opacity which stained widely

Fig. 1—Chronic ulcerative blepharitis, subacute conjunctivitis and pyoderma of the face, secondary to coagulase positive hemolytic *Staphylococcus aureus*. The organism was resistant to penicillin 10,000 units per cubic centimeter *in vitro*. The photograph was taken at the beginning of treatment.

with fluorescein on April 29, 1943. The eye was red and painful. The corneal ulceration progressed. Photophobia, lacrimation, headache and ocular pain were constant. The corneal epithelium would not regenerate. Conjunctival cultures showed the presence of a gram negative bacillus and a gram positive bacillus, unidentified. Vision was reduced to hand movements. Enucleation of the eye was seriously considered. Instillation of penicillin, 250 units per cubic centimeter, 3 drops in the left eye every fifteen minutes for two hours and thereafter every half hour, was begun on May 25. On June 4 dosage frequency was reduced to every three hours between 7 p. m. and 9 p. m. Penicillin therapy was discontinued on June 19. Twenty-four hours after treatment was instituted there was definite clinical improvement. The ciliary flush had diminished and the crater of the corneal ulcer was smaller. Forty-eight hours after treatment pain had diminished to such an extent that the patient stated he felt more comfortable than he had felt for a long time. The corneal ulcer slowly healed, forming a vascularized interstitial scar. The conjunctival cultures grew many organisms. *Staphylococcus albus*, gram positive and gram negative bacilli, diphtheroids and spore bearing bacilli were noted. There was still slight staining of the cornea on June 9. On June 16 the left eye was white, the patient was symptom

free and the cornea did not stain. Vision of the left eye was ability to count fingers at a distance of 1 foot. A relapse did not occur. It is reasonably certain that this eye was saved by penicillin therapy.

An officer aged 28 suffered a chemical burn of both eyes and eyelids on December 8, 1943. The left eye healed with minimal corneal opacities and vision of 20/30—2. The right

Fig. 2—Patient illustrated in figure 1 one month after local treatment with penicillin 1,000 units per cubic centimeter. His blepharoconjunctivitis has improved considerably. *Staphylococcus aureus* is still present. The facial infection was not treated.

Fig. 3—Nutrient agar cup plate seeded with *Staphylococcus aureus* in the same case as figures 1 and 2. The cups contained a solution of penicillin 10,000 units per cubic centimeter. The inhibition rings are minimal. Growth would have been inhibited on most of the plate with a sensitive organism.

cornea remained insensitive, with a low grade superficial ulceration, great photophobia and profuse lacrimation. A hordeolum appeared on the lower left eyelid on Feb. 29, 1944. Conjunctival

cultures revealed the presence of nonhemolytic *Staphylococcus aureus*, coagulase positive, and nonhemolytic *Staphylococcus albus*, coagulase negative. Local penicillin therapy was instituted to prevent infection of the cornea. Three drops of sodium penicillin 1,000 units per cubic centimeter was instilled hourly in the right eye. Treatment was discontinued on March 5. The hordeolum was incised and healed rapidly. The cornea did not become infected. Sensation returned to the cornea during penicillin therapy. A small indolent superficial ulcer was still present when penicillin was discontinued. The corneal ulcer did not heal, and symptoms of irritation remained. On March 17 *Staphylococcus aureus*, coagulase negative, was cultured from the conjunctiva. There was evidence of an acute pharyngitis and cervical adenitis. Local penicillin therapy was resumed every two hours. Atropine mydriasis was maintained. Treatment was discontinued on April 4, at which time the right cornea did not stain. Photophobia and lacrimation had diminished greatly. His right eye was more comfortable than it had been for weeks. Conjunctival cultures were negative. The right cornea stained slightly on two occasions after penicillin was discontinued. Vision was 20/30—2 in each eye on May 13.

This case illustrates the advisability of obtaining and maintaining a sterile conjunctiva in the presence of chronic corneal disease. Penicillin therapy was apparently discontinued too soon in the first instance. No other medication afforded such prompt objective and subjective relief.

Keratitis Dendritica.—Two patients with monocular keratitis dendritica, recurrent in scarred corneas, were treated with penicillin locally and scopolamine mydriasis, without closing the eyes. Penicillin 1,000 units per cubic centimeter every two hours was used in both cases. Cultures in the first case were sterile. At the end of twenty days of treatment there still remained a small staining area on the cornea. A cross infection by a gram negative bacillus resembling the Koch-Weeks or influenza bacillus occurred. The remaining ulceration of the cornea was treated twice by topical application of 95 per cent alcohol, after which final healing was obtained. The second patient was infected with hemolytic *Staphylococcus aureus* and an unidentified gram negative bacillus. Penicillin therapy was terminated after twenty-three days by a relapse of malarial fever. At this time there remained a small staining area on the cornea. The cornea healed immediately after subsidence of the malarial attack. Conjunctival cultures were sterile after seven days' therapy. This patient has since relapsed. The presence of a nonhemolytic *Staphylococcus albus*, coagulase negative, was demonstrated. The ulceration progressed under topical applications of alcohol. Penicillin therapy was resumed. A minimal staining area finally healed when the eye was patched. Subjective symptoms were minimal in both patients, although the pupil of the diseased eye was dilated and the eyes were unpatched. No increase occurred in previous corneal scarring. The value of the penicillin therapy was problematic. The element of the curative advantage of hospitalization cannot be overlooked.

Chronic Blepharoconjunctivitis.—Several patients were treated locally with penicillin solution alone and combined with penicillin ointment. A staphylococcus was the chief infective agent in most instances. The majority of these patients responded promptly to treatment. A few relapses occurred. The patients were

treated again with penicillin locally, with good results. One instance of complete resistance to penicillin was encountered. It is doubtful that penicillin will cure noninfected allergic conjunctivitis.

Orbital Cellulitis.—Several cases of orbital cellulitis were seen in consultation with the ear, nose and throat section. Early and large doses of penicillin parenterally gave satisfactory results when the causative agent was sensitive to penicillin. Unless orbital cellulitis and cavernous sinus thrombosis are seen early and react favorably to heroic treatment with penicillin, surgical intervention is required also. A more detailed report of this type of disease belongs to the ear, nose and throat practitioner.

Trachoma.—Unsatisfactory results were obtained in 1 case of bilateral trachoma, secondary stage, treated with penicillin 1,000 units per cubic centimeter locally every two hours for nine days. The disease progressed during treatment. Expression of the follicles with Knapp's roller forceps followed by local and systemic sulfonamide therapy brought immediate improvement.

Penetrating Injuries.—The studies of von Sallmann and Meyer¹⁷ suggest the inadequacy of local treatment by instillation of penicillin drops on the cornea and in the lower conjunctival cul-de-sac in the treatment of experimental acute suppurative intraocular infections in rabbits. It is recommended until further clinical and experimental evidence is available that the technique of Cashell¹⁸ and Grant¹⁸ be followed in treating injured eyes. They instilled penicillin directly into the anterior chamber, with favorable results.

Cashell¹⁸ "irrigated" the anterior chamber in 2 cases of perforating injury. The end results were good. A postoperative infected cataract, treated for thirty-three days, was included in this group. In 3 other cases "definite infections of the anterior chamber cleared with penicillin, but chronic cyclitis supervened." These eyes were excised.

Grant¹⁸ reported striking improvement in an eye suffering from exudative iridocyclitis secondary to a penetrating wound and treated with penicillin thirty-four days after injury. Aqueous, 0.25 cc., was withdrawn from the anterior chamber through a hollow needle and replaced by an equal amount of penicillin solution 250 units per cubic centimeter. Forty-eight hours later recovery had begun and marked the turning point in saving the eye. Further penicillin treatment was not required.

Adequate penicillin treatment of an infected perforating eye injury or a metastatic eye infection entails combined parenteral, local and intraocular medication. Continuous intravenous drip of 200,000 Oxford units in twenty-four hours or in less acute cases intramuscular injection of 25,000 units at three hour intervals is recommended. Local therapy may consist of instillation of penicillin 1,000 units per cubic centimeter half-hourly or hourly, supported by the withdrawal of aqueous and replacement by penicillin 1,000 units per cubic centimeter of isotonic solution of sodium chloride. The withdrawal of aqueous when a high level of penicillin in the blood has been obtained should give a maximum secretion of penicillin in the secondary

17. von Sallmann, L., and Meyer, K.: Penetration of Penicillin into the Eye, *Arch. Ophthalm.* 31: 1 (Jan.) 1944.

18. Grant, R. B., Jr.: Personal communication to the author.

aqueous, if such secretion occurs. It is doubtful that more than 0.4 cc. of aqueous can be replaced by penicillin. The removal of penicillin from the anterior chamber by natural filtration and dilution by the remaining aqueous and the secondary aqueous would give a primary dilution of not more than 200 units per cubic centimeter of aqueous with further rapid dilution. The effective level of penicillin in the aqueous and the rapidity with which this level is reduced by normal drainage have not been ascertained.

Prophylaxis in Eye Injuries.—The use of penicillin as a prophylactic measure in eye injuries is a justifiable empirical measure. Other therapeutics also should be employed.

An aviator aged 21, who suffered a contusion of his left eyeball, presented an instance of such therapy. The cornea was abraded. There was a hyphema. Vision was reduced to 5/100. Conjunctival cultures revealed hemolytic *Staphylococcus albus*, coagulase positive. Four days after injury, treatment was started with penicillin 15,000 Oxford units intravenously every three hours and 3 drops of 1,000 units of penicillin per cubic centimeter of isotonic solution of sodium chloride instilled in the left eye half-hourly for eight doses and then hourly. Treatment was continued for six and a half days. The pupil was dilated and a small posterior synechia broken by scopolamine. A diffuse deep interstitial haze developed on the temporal side of the left cornea concurrent with increased hemorrhage in the anterior chamber. The eye culture was negative in one day. On completion of penicillin therapy the corneal haze was reduced to a small linear peripheral scar. The vision in the left eye was 20/20 slowly. The interior of the eye was normal.

This officer presented a therapeutic problem. His training was within one month of completion. There was clinical evidence of severe trauma to his left eye. A pathogenic organism was present in the conjunctival cul-de-sac of his injured eye. This eye manifested a severe inflammatory reaction involving the conjunctiva, episclera, sclera, cornea and iris. There was a choice of therapy between artificial hyperpyrexia and penicillin. Penicillin was chosen because of the presence of a hemolytic *Staphylococcus albus*, coagulase positive.

Recurrent Post-Traumatic Iritis.—The history of an injured soldier with iritis was enlightening:

A white soldier aged 20 was injured by a dynamite explosion in November 1943. On Feb. 29, 1944 he reported with iritis of his left eye. Examination revealed bilateral corneal scars and traumatic cataracts. There was evidence of previous iritis of his right eye. Sand had perforated his left eye. Conjunctival cultures were sterile. Penicillin was administered intramuscularly, 25,000 units every three hours for four and a half days and reduced to 15,000 units for two days. Mydriasis by atropine was maintained. Recovery was prompt. No sequelae remained. A slightly discharging left amputation stump was not affected by penicillin therapy. On March 20 iritis recurred in his left eye. Treatment of this attack of iritis consisted in keeping the pupil dilated with scopolamine for six days. An aqueous flare, which was present in both attacks, had then disappeared. The blood vessels of the iris were still slightly engorged. Ocular pain disappeared after twenty-four hours of treatment in both attacks of iritis.

This patient exemplified the difficulty of clinical research. It is doubtful that penicillin was of any benefit in this case.

MEDICATION AND DOSAGE

The following routes of administration are applicable in eye diseases:

Local.—Instillation in the eye: Dosage 250 to 10,000 Oxford units dissolved in 1 cc. of isotonic solution of

sodium chloride or distilled water, pH 7.7, administered hourly in acute conditions, every two hours in subacute conditions and not less frequently than every three hours. Cashell¹⁰ reported good local results with less frequent and weaker dosage. He did not report any penicillin fast organisms developing during treatment. Fresh solutions kept in a commercial refrigerator deteriorate very slowly. It has been the practice to replace eye solutions, kept at room temperature, after forty-eight hours. The solutions are still potent in vitro.

Ophthalmic ointment: Dosage 250 to 500 units incorporated in a gram of ointment base. Commercial petrolatum or hydrous wool fat, 25 per cent combined with cold cream 75 per cent showed a satisfactory zone of diffusion of penicillin in vitro on seeded plates. Penicillin ointment still showed appreciable penicillin activity after six months in a commercial refrigerator. Diffusion activity lessens appreciably after twenty-five days at room temperature. One specimen was still potent after forty-five days at room temperature.

Intraocular: Aqueous is withdrawn from the anterior chamber through a needle and replaced by penicillin. Local or general anesthesia is employed. Incomplete incision of the cornea at the site of puncture simplifies passage of the needle. Freshly prepared penicillin 500 to 1,000 units per cubic centimeter of isotonic solution of sodium chloride is used. Aqueous to the extent of approximately 0.4 cc. may be withdrawn with impunity. The strength of the injected penicillin is immediately reduced by the remaining aqueous and is soon further reduced by removal by normal filtration and dilution by new aqueous.

Parenteral.—*Intramuscular:* Dosage from 15,000 to 25,000 units in isotonic solution of sodium chloride or fractionally distilled pyrogen free distilled water injected into the thigh, gluteal or upper back muscles every three hours.

Intravenous: Intravenous solutions are made daily. Pyrogen free isotonic solution of sodium chloride and 5 per cent dextrose are used as solvents. Intermitent dosage 15,000 to 25,000 units injected slowly every three hours. Continuous drip dosage 200,000 units of fresh penicillin dissolved in 2,000 cc. (2 liters) of saline or dextrose solution administered in twenty-four hours at a basic drip rate of approximately 30 drops per minute. Treatment may continue for several days. Larger doses have been given without ill effect. A dextrose solution is recommended in the presence of kidney disease to avoid possible anasarca.

Intrathecal: Riba¹⁶ has found the administration of 25,000 units in 2.5 cc. of isotonic solution of sodium chloride by replacing an equal amount of spinal fluid very satisfactory. The medication is repeated at forty-eight hour intervals or oftener in acute disease. Penicillin accumulates in the spinal fluid.

Staphylococcal infections require three or four times as much penicillin as streptococcal infections. Queen¹⁹ has found the minimum effective blood level for the staphylococcus 0.3 unit per cubic centimeter of circulating blood. A concentration of 0.03 unit per cubic centimeter is sufficient for streptococcal infections. It has been the practice to continue reduced treatment for two or three days after a clinical cure has been obtained.

19. Queen, F. B. Personal communication to the author.

Penicillin may be discontinued sooner in acute infections than in chronic infections without fear of relapse. Penicillin is thermolabile. A p_H of 7 to 7.7 is recommended for solutions and ointments. Penicillin stock solutions should be refrigerated.

COMPLICATIONS

Most complications, such as phlebitis, pyrexia, pain at the site of injection, vascular and sympathetic disturbances and muscular cramps, have largely disappeared with the use of purer penicillin.

Generalized allergy with urticarial manifestations, with or without fever, has occurred. Thrombophlebitis may occur at the site of prolonged intravenous injection. Local allergy of a mild degree affecting the eyelids and skin below the eyes is easily controlled by covering the eyelids and skin with a neutral waterproof emollient.

An unusually severe allergic reaction was obtained, in 1 instance following instillation of 4 drops of sodium penicillin 1,000 units per cubic centimeter into both eyes at hourly intervals. There was evidence of redness and puffiness of the eyelids before the last drop was administered. The eyelids then became very red, hot and nearly closed by edema. The conjunctiva was acutely congested. The mucous membrane of the nose and throat was red, dry, painful and glossy. A temperature of slightly more than 100 F. was carried for four days. The patient complained of malaise similar to that noted after an inoculation with antityphoid vaccine. He was hospitalized for a week. The penicillin used in this case was tested on another patient and on a rabbit with negative results. A skin patch test elicited a negative reaction. Cutaneous disturbances had been experienced by the patient on ingestion of certain sea foods, chocolate, strawberries and rice.

The complication of cross mixed infection in ocular diseases is not so important as in general infections but may retard recovery. There is evidence suggesting that with the extermination of a virulent penicillin sensitive organism present in a given case the remaining nonsensitive organisms are not very pathogenic.

Local irritation caused by the early batches of penicillin has disappeared with purification of the drug.

Inadequate early treatment with penicillin may cause reduction of sensitivity of the organism treated or even penicillin fastness. In such cases intensive treatment with penicillin may be tried with some prospect of obtaining clinical improvement with

lessened virulence of the organism. The combined or alternate use of sulfonamide drugs should be tried.

The criteria of successful penicillin therapy are speedy relief of a patient's symptoms and rapid subsidence of infection.

COMMENT

Penicillin is the drug of choice in the treatment of ophthalmic diseases secondary to infection with gonococci, streptococci and sensitive staphylococci. Penicillin should be given a trial in the treatment of diseases caused by *N. meningitidis*, *N. catarrhalis* and pneumococci. The use of penicillin is optional in the treatment of infections caused by *C. diphtheriae*, *Cl. welchi*, *Actinomyces bovis* and *Treponema pallidum*.

Fig. 5.—Acute allergy to local penicillin followed bilateral instillation of 4 drops of penicillin 1,000 units per cubic centimeter. Acute edema of the eyelids, congestion of the sclera, conjunctiva and the mucous membrane of the nose and throat with pyrexia and malaise were manifested.

The relief afforded by penicillin when it is effective is usually prompt, in some instances startling and usually better than that afforded by other modes of medication. Considerable penicillin can be saved by identification of the bacteria present in a disease before treatment is instituted. A primary sensitivity test is recommended in chronic infections caused by staphylococci. An unfavorable early response to penicillin therapy suggests a reappraisal of the case. A virulent resistant organism may be present.

In diseases caused by a noninfectious process such as allergy the removal of a secondary infection by penicillin is helpful but obviously leaves the primary problem unsolved.

The use of penicillin as a prophylactic in certain intraocular operations and ocular injuries is recommended. Experience suggests that it is a better practice to give an overdose of penicillin rather than an underdose. It is anticipated that the dosage of penicillin will be stabilized in the near future, but, as with all drugs, the dosage will be subject to modification in acute and resistant diseases.

Early and large doses of penicillin are indicated in orbital cellulitis secondary to infection in the paranasal sinuses and adjacent venous dural sinuses.

Penicillin solutions, because of their instability, do not lend themselves to office and home medication as readily as more stable drugs. Penicillin solution 1,000 units per cubic centimeter of isotonic solution of sodium chloride tested in vitro on a nutrient agar cup plate seeded with Oxford staphylococci produced an inhibition ring 45 mm. in diameter. After twenty-one days at room temperature the diffusion ring was still 40 mm. in diameter. Penicillin ointment is reasonably stable for at least a month at room temperature and for six months in a commercial refrigerator. There is a constant danger of contamination of penicillin by resistant organisms. Heat destroys penicillin; therefore resterilization is not feasible.

It is anticipated that in private practice penicillin will frequently have to be used in an empirical manner. In spite of this handicap it will be found that a valuable and dependable drug has been added to the armamentarium of the ophthalmologist.

Fig. 4.—Right eye of patient with bilateral acute conjunctivitis superimposed on a chronic follicular conjunctivitis and associated with a head cold. Alpha hemolytic streptococci and coagulase negative hemolytic *Staphylococcus albus* were present in both eyes. Conjunctival cultures were sterile after five days' local treatment with penicillin 1,000 units per cubic centimeter. Treatment was continued for eight more days because of turgid palpebral conjunctiva.

THE USE OF PENICILLIN IN DISEASES OF THE EAR

CAPTAIN CLIFFORD A. SWANSON (MC), U.S.N.

AND

LIEUTENANT DANIEL C. BAKER JR. (MC), U.S.N.R.

Penicillin has been proved to be a very powerful antibacterial agent. Much has been written about its value in the treatment of many severe and previously often fatal infections. Until recently its use was restricted to overwhelming infections which did not respond to other forms of therapy. Lately the increased production of the drug has made enough available to permit its employment in more common infections, such as those of the ear.

Penicillin is a powerful antibacterial substance produced by *Penicillium notatum* in ordinary nutrient broth.¹ It is highly soluble, relatively unstable and easily destroyed by dilute acids. It is hygroscopic and rapidly loses its activity if exposed to air, but it retains its activity for twenty-four hours if absolutely dry.² Penicillin is not affected by pus, blood, serum or the products of breakdown of tissue. The number of organisms has little effect on its bacteriostatic action. Penicillin inhibits the growth of bacteria while the body defenses, humoral and cellular, destroy the organisms.³ Purified penicillin in dilution of 1:25,000,000 will completely inhibit the growth of *Staphylococcus aureus*⁴ and is free from toxic reactions.

Hobby, Meyer and Chaffee⁵ made studies of the susceptibility of various strains of many organisms to penicillin. The susceptible organisms are pneumococci, hemolytic *Streptococcus*, staphylococci, meningococci, gonococci, *Streptococcus viridans*, *Bacillus subtilis*, *Clostridium welchii*, *Clostridium septicum*, *Clostridium histolyticum*, *Bacillus sporogenes*, *Bacillus oedematis*, *Bacillus sordelli*, lactobacilli and *Cryptococcus hominis*. Insusceptible strains are *Hemophilus influenzae*, *Escherichia coli*, *Salmonella paratyphi A*, *Salmonella enteritidis*, *Bacillus pyocyaneus*, *Bacillus fluorescens*, *Bacillus prodigiosus*, Friedländer's bacillus, *Staphylococcus albus* (1 strain), *Micrococcus albus* (1 strain), *Monilia albicans*, *Monilia krunzei* and *Monilia caudida*. Gardner⁶ has observed morphologic changes in all the rod shaped organisms that showed any inhibition by penicillin. These changes are attributed to a failure of fission; growth proceeds, but division and separation of the cells do not follow in due course.

Salts of penicillin, such as ammonium, sodium and calcium, have been prepared for clinical use. The quantity of the drug used is expressed in terms of the Oxford unit. The latter is defined as that amount of penicillin which, when dissolved in 50 cc. of meat

extract broth, just inhibits completely the growth of the test strain of *Staphylococcus aureus*.⁷

According to Dawson and Hobby,⁸ the establishment of correct dosage and frequency of administration are problems of great complexity. They recommend that the sensitivity of the infecting organism be tested whenever possible in cases which do not respond satisfactorily. Penicillin can be administered by continuous subcutaneous infusion, continuous intravenous injection, intramuscular injection, intrathecal injection and local instillation. The advantages and objections to these routes have been discussed by Bloomfield, Rantz and Kirby.⁹ The more severe infections are treated by continuous intravenous injection, because a higher concentration of penicillin in the blood can be obtained. When the drug is injected intramuscularly, the blood level is lower but is more evenly sustained. If a single intravenous injection of penicillin is given, about two thirds of it will be recovered promptly in the urine.¹⁰ In his discussion in a symposium on "Antibiotic Agents," Keefer¹¹ reported that there was no universal agreement on dosage, best method of administration or duration of treatment, stating that the final answer

Fig. 1 (case 2).—A, mastoid cavity at completion of simple mastoidectomy; B, insertion of the rubber tube.

to these questions will come only from the study of more cases.

The Penicillin Committee at the National Naval Medical Center believes that the intramuscular administration of the drug is the most practicable. In order to ensure the therapeutic effectiveness of the drug, this committee stresses the importance of two conditions: (1) the maintenance of adequate nutrition and a positive nitrogen balance in patients receiving the drug and (2) accurate preliminary bacteriologic studies to determine that the pathogen is an organism susceptible to the drug.

Infectious diseases of the ear can be effectively treated with penicillin because the anatomic structure of the ear permits the local administration of the drug and because the organisms causing most acute infections of the ear are usually in the group considered to be susceptible to the drug. Fowler¹² made a study of 452

consecutive cases of acute otitis media. If his statistical analysis of the causative organisms in that series is considered representative of their relative incidence, then 90 per cent of the organisms are susceptible to penicillin.

Fig. 2 (case 2)—Closure of wound for rubber tube

In this study the sodium salt was used. It was given either by continuous intravenous injection, intramuscular injection or local instillation. In 1 instance a combination of the intramuscular and local routes was used.

Fig. 3 (case 2)—A, wound covered with gauze impregnated with penicillin ointment and injection of penicillin solution into mastoid cavity; B, rubber tube sealed after injection of penicillin; C, tube protruding through dressing in order to facilitate aspiration of exudate and instillation of penicillin.

METHOD AND RESULTS

1. *Acute Otitis Media*.—In acute otitis media, penicillin is administered by intramuscular injection. The amount of drug necessary to combat the infection will

vary according to its causative organism and severity. Staphylococcal infections, as a rule, require a greater amount of penicillin than those due to streptococci. The drug should be continued after the patient has appeared to recover to avoid possible relapse.

CASE 1.—G. E. G., a white youth aged 18, was admitted to the hospital with the history of a sense of fullness in his left ear of one week's duration. His temperature was 100 F. Blood examination revealed red blood cells 4,700,000, white blood cells 12,450, hemoglobin content 13.5 Gm.

Examination showed severe congestion of the mucosa of both nasal chambers. The sinuses were clear. The left ear drum was red and thickened, and there was a pulsating discharge from a posterior inferior perforation. Cultures showed the organism to be a hemolytic streptococcus. He was given sulfadiazine 4 Gm. initially and then 1 Gm. every four hours. His left ear continued to discharge, and eleven days later his temperature, which had been normal, began to fluctuate between 99 and 101 F. The sulfadiazine level at this time was 11 mg. per hundred cubic centimeters of blood.

X-ray examination of the mastoids revealed the right mastoid to be well developed, well aerated and apparently clear. The left mastoid showed a less degree of development than the

Fig. 4 (case 2)—Wound at the end of seven days, showing clear sterile exudate being expressed from the rubber tube prior to its removal.

right, and there was rather poor aeration of the cells. In the squamous portion of the left mastoid there was what seemed to be destruction of trabeculae between the air cells, and many of these cells appeared to be filled with material of soft tissue density. The impression was destructive mastoiditis, left.

Sixteen days after onset of infection, at the time when it appeared that a mastoidectomy would be necessary, penicillin was administered. Sulfadiazine was discontinued, and the patient was given 20,000 units of penicillin intramuscularly every three hours day and night for a period of two weeks.

His temperature became normal twenty-four hours after the start of penicillin and the ear became dry on the seventh day of penicillin therapy, which extended over a two week period in all. At the end of this time his left ear drum returned to normal and the patient was discharged from the hospital. He received a total of 2,260,000 units of penicillin.

It would appear that penicillin was effective in sparing this patient an operation.

Fourteen additional cases of acute otitis media were successfully treated with penicillin. The pathogens obtained on culture from these patients are listed in the table. The penicillin was given by intramuscular injection. The amount of the drug required varied from

360,000 to 1,140,000 units per patient over a period varying from five to fourteen days.

2. *Acute Mastoiditis*.—When surgical intervention is done for acute mastoiditis it can be supplemented by penicillin administered either by intramuscular injection or by local instillation into the mastoid cavity. The Floreys³ employed the latter method by means of controlled drainage in 22 cases of surgical mastoiditis. They inserted a rubber tube into the mastoid cavity and closed the incision completely except to accommodate the tube. Penicillin was then instilled into the cavity through the tube, which was then sealed off. Afterward every six hours the exudate was aspirated from the cavity and fresh penicillin was instilled through the tube, which was again sealed. Free drainage was not allowed at any time. This routine was employed for a period of five days, and an average of 17,300 units per case was required. The ear usually became dry within a period of five days, and primary healing resulted in 19 of the 22 patients. The second and third patients received the drug both intramuscularly and locally after the method of Florey with slight modification, the other only locally:

CASE 2.—S. B. H., a white woman aged 25, was admitted to the hospital with the history of having had a discharging right ear for three weeks. She had received a total of 17 Gm. of sulfadiazine and 50 Gm. of sulfanilamide before entering the hospital. In the preceding week she had complained of noc-

to lie outside the dressings. The incision was closed tightly except for the rubber tube passage. Fifteen cc. of a solution containing 1,000 units of penicillin per cubic centimeter was injected through the rubber tube into the mastoid cavity, and the external canal was packed tightly with gauze impregnated with penicillin.

Thereafter, every six hours during a period of forty-eight hours, the wound was aspirated and 3 cc. of the penicillin solution was injected into the mastoid cavity via the rubber tube (for illustration of technic see figures 1 through 4). During the same period the patient received 30,000 units of penicillin intramuscularly every three hours. On the third day the instillation of penicillin into the mastoid cavity was discontinued but the rubber tube remained completely sealed off, so that there was no drainage at any time. Also on the third day the intramuscular injections of penicillin were reduced to 15,000 units every three hours. On the seventh postoperative day the intramuscular injections were discontinued and the rubber tube was removed from the mastoid cavity. On the eighth postoperative day the incision was healed, the middle ear was dry and the perforation of the ear drum had healed. The patient had no further trouble with her ear. During the course of her disease she received a total of 1,905,000 units of penicillin intramuscularly and locally. Penicillin caused no noticeable untoward reaction and appeared to have shortened her convalescence greatly.

CASE 3.—C. J. S., a white man aged 25, was admitted to the hospital with acute appendicitis. An appendectomy was performed, and six days after operation he complained of a sore throat. On the seventh day he had severe pain and a serous discharge from his right ear. He was transferred to the eye, ear, nose and throat service the same day, with the diagnosis of acute otitis media, right ear. He was given sulfadiazine 4 Gm. initially and 1 Gm. every four hours afterward day and night. Cultures of the exudate from the right ear showed the presence of a hemolytic streptococcus. His right ear continued to discharge, and on the tenth day of the ear infection he had considerable pain over the right mastoid process and right facial paralysis. There was x-ray evidence of a right mastoiditis. The sulfadiazine level at this time was 6 mg. He was given a blood transfusion of 250 cc., and a simple mastoidectomy was immediately performed. Operation revealed pus under pressure in the mastoid cells bordering on the digastric groove, with no breaking down of the cells. At the completion of the operation a rubber tube was inserted into the wound, so that one end came in contact with the antrum and the other end protruded through the incision. The wound was closed except for the rubber tube passage. For eight days after operation once a day 3 cc. of a solution containing 250 units of penicillin per cubic centimeter was instilled into the mastoid cavity through the rubber tube and sealed in. On the ninth postoperative day the rubber tube was removed. On the tenth day the facial paralysis began to disappear, and after two weeks the patient had almost complete restoration of motion in the right side of his face. After the operation there was no purulent drainage at any time from the mastoid wound. A total of 6,750 units of penicillin was used.

In this case penicillin appeared to shorten convalescence and hasten recovery from facial paralysis.

3. *Acute Labyrinthitis*.—Penicillin can be administered by continuous intravenous injection for the treatment of acute labyrinthitis. In the following case treatment was successful by this means.

CASE 4.—L. C. P., a white man aged 33, a physician, was admitted to the hospital on Sept. 10, 1943 with the history of having had vertigo, tinnitus and deafness of his left ear for one month and severe pain in his left ear for one week. In September 1942 he had had an osteomyelitis of his twelfth dorsal vertebra caused by hemolytic *Staphylococcus aureus* and successfully treated by operation and a sulfonamide drug. In March 1943 he had had empyema of the gallbladder caused by the same organism and successfully treated by surgery and a sulfonamide drug. In May 1943 he had had what appeared

Organisms in Fifteen Cases of Acute Otitis Media

Organism	No. of Cases
<i>Staphylococcus aureus</i>	2
Hemolytic <i>Staphylococcus aureus</i>	2
Hemolytic streptococcus.....	8
<i>Pneumococcus type 1</i>	1
Hemolytic <i>Staphylococcus aureus</i> and hemolytic streptococcus.....	2

tural pain over the right mastoid and general malaise. Examination was negative except for the ear. There was a thick purulent discharge in the right canal. The ear drum showed a posterior perforation, and the mucosa of the middle ear was red and thickened. Pain was elicited on pressure over the mastoid.

X-ray examination of the mastoids disclosed that on the left side the mastoid cells were well aerated. On the right side the cells in the temporal portion of the mastoid were indistinct and the bony separations of the mastoid cells were poorly outlined and most of the cells appeared blurred. There seemed to have been definite bony destruction of the trabeculae separating some of the cells in this area.

The patient's temperature was normal on admission but fluctuated between normal and 99.2 F. for the first few days. The sedimentation rate showed a fall of 31 mm. at the end of an hour. Blood examination revealed red blood cells 3,000,000, hemoglobin content 10 Gm. and white blood cells 8,300. The urinalysis was negative.

She had lost 6 pounds (2.7 Kg.) in three weeks and felt generally below par. Soon after admission she was given 30,000 units of penicillin intramuscularly every three hours. Three days after admission she was given a transfusion of 250 cc. of whole blood. The following day a simple mastoidectomy of the right ear was performed. Operation revealed free pus, considerable breaking down of the mastoid cells in the region of the tip and over the lateral sinus, pathologic exposure of the sinus and thickening of its wall. A hemolytic streptococcus was cultured from the pus.

At the completion of the operation a small rubber tube of 14 French caliber was inserted into the wound, one end being left in contact with the antrum and the other end protruding through the incision to a length which permitted its opening

to be an attack of Ménière's syndrome on the left side without any subsequent complaints until his present illness.

On admission his temperature was 99.4 F. He had nystagmus to the right on right lateral gaze and slight nystagmus to the right on upward gaze. There was no evidence of active

4. *Chronic Otitis Media*.—In special instances chronic otitis media can be treated successfully by the local instillation of penicillin into the middle ear. The patient who has a chronic discharging ear caused by an organism susceptible to the drug and has a large perforation of the ear drum with no evidence of granulations or cholesteatoma is best suited for penicillin therapy. The pneumatic otoscope can be used to force the drug into the middle ear,¹³ and the penicillin can be sealed into the ear by means of cotton impregnated with a bland ointment (see figures 5 and 6 for illustration of technic).

CASE 5.—H. F. J., a white man aged 32, was referred to the outpatient department for treatment of a right chronic otitis media. For several years he had had continuous discharge from his right ear varying in amount. Examination showed a moderately thick tenacious discharge in the right external canal and a large anterior inferior perforation of the right ear drum; there was no granulation tissue. X-ray study showed evidence of a chronic mastoiditis on the right side. There was no evidence of a cholesteatoma. Over a period of years the patient had received different kinds of treatment, including boric acid and alcohol drops, Sulzberger powder and sulfonamide powder. Cultures showed the presence of a *Staphylococcus aureus*.

He was treated in the outpatient department. A few drops of a solution containing 250 units of penicillin per cubic centimeter were instilled into the right ear while the patient's head was inclined to the left. The penicillin was forced into the middle ear through the perforation by means of a pneumatic otoscope. The canal was then filled with the penicillin solution, and the drug was trapped in the ear by means of cotton impregnated with a bland ointment. The patient was given a small bottle of the solution to take home and was told to remove the cotton and to dry the canal after six hours. He was instructed to lie on the left side before

Fig. 5 (case 5).—A, instillation of penicillin into the external canal; B and C, use of pneumatic otoscope in chronic otitis media.

disease in the nose and throat. His right ear was normal; his left ear drum was injected. The left ear was totally deaf. Blood examination revealed red blood cells 4,720,000, hemoglobin content 13 Gm., white blood cells 7,750. Blood culture and urinalysis were negative. During the first twenty-four hours his temperature fluctuated between normal and 99.4 F. by mouth. He complained of severe pain deep in the left side of his head, which could be controlled only by large doses of morphine. The neurologic examination was negative except for the labyrinthine disturbances. X-rays of the skull and mastoids showed no evidence of disease.

It was the opinion of the neurologic service that the patient had an osteomyelitis of the left petrous pyramid, with involvement of the labyrinth, and that the infection was probably metastatic in origin.

The pain in his left ear became progressively worse and on his sixth hospital day a left myringotomy was performed with nitrous oxide-oxygen anesthesia. Clear fluid was obtained from the left middle ear. Cultures showed the organism to be hemolytic *Staphylococcus aureus*. In view of the history of previous severe infections with the same organism and the possibility that the middle ear disease might be secondary to cranial osteomyelitis, it was decided to give the patient penicillin. After the myringotomy, penicillin was begun by continuous intravenous injection and continued for five days. He got a total of 455,000 units. It is noteworthy that the patient was free from pain twenty-four hours after penicillin was begun and that his temperature returned to normal in forty-eight hours. His left ear was dry on the fifth day, and his ear drum gradually returned to normal. Subsequent studies confirmed the total loss of hearing in his left ear and revealed a total loss of vestibular response to left caloric stimulation.

Apparently this patient had an acute labyrinthitis on the left side, with the exudate working its way through into the middle ear. Its metastatic origin is supported by the identity of its causative organism with that of two previous infections, one of which was certainly hematogenous. He has been left with complete loss of cochlear and vestibular function on the left side. There has been no recurrence of tinnitus or vertigo.

Fig. 6 (case 5).—Penicillin sealed in external canal and middle ear by cotton impregnated with ointment

going to bed and to instill a half medicine dropper of the penicillin solution into his right external canal and to trap the solution with cotton impregnated with ointment, placed at the external meatus. This routine was carried out for a period of

13. Canon, R. T.: Personal communication to the authors.

eight days. His ear became dry and has remained dry for a period of six months. A total of 10,000 units of penicillin was used. The drug had no effect on the perforation.

One other case of chronic otitis media due to *Staphylococcus aureus* was successfully treated by the same method, but several other cases did not respond satisfactorily.

SUMMARY

A study was made of the use of penicillin in diseases of the ear. The drug was found to be of value in the treatment of acute otitis media, acute mastoiditis, acute labyrinthitis and chronic otitis media. A technic was developed for the use of penicillin by local instillation into the external canal and middle ear as well as into the postoperative mastoid cavity.

Penicillin has been employed with substantial benefit in many instances in which other forms of therapy had failed. It was possible either to avoid surgical intervention for acute mastoiditis or to use the drug as a supplement to surgery with significant help.

When the drug is instilled into the mastoid cavity after operation, healing is prompt and the period of convalescence is shortened. Penicillin is the most powerful chemotherapeutic agent available to combat acute otitis media, acute mastoiditis and their complications.

USES OF PENICILLIN IN DISEASES OF THE NOSE AND THROAT

CAPTAIN F. J. PUTNEY

MEDICAL CORPS, ARMY OF THE UNITED STATES

Penicillin must not be used indiscriminately, but its effectiveness in combating susceptible infections is benefiting practically every branch of medicine. We have employed it at Bushnell General Hospital since April 1943 chiefly in overwhelming infections and complications of ear, nose and throat diseases when life was endangered. In the entire series of 19 cases the organisms were those which are sensitive to penicillin, in general the group of cocci. This presentation will be limited to the 9 cases classified as instances of sinus complications.

Originally penicillin was administered intravenously, either by repeated venous punctures every two hours or by continuous drip, but both of these methods have largely been supplanted by the intramuscular route. Continuous drip injection may be preferable for extremely ill persons with grave infections when a high prolonged blood concentration is desired. After the hazardous phase has subsided, intramuscular use may be substituted. In general, the dosage we have employed was 25,000 units intramuscularly every three hours, which was reduced to 15,000 units as the patient improved, the three hour period being maintained. Penicillin used locally is also bacteriostatic, but we have not depended on local use alone and have usually combined local with systemic administration. The organisms in all except 1 of this group of cases remained sensitive to the drug. In 1 case the organism became penicillin fast after several weeks of treatment. When there has been no improvement in the appearance of a wound and continuation of purulent drainage after three

or four days of penicillin therapy, one should suspect that the organism is resistant to the drug and sensitivity tests are indicated. In our experience failure to respond to penicillin has been due to a resistant bacterial strain.

In the early stages of using this drug while endeavoring to determine its range of usefulness, large doses were employed for many weeks without other forms of treatment. The results were disappointing in that healing was not obtained even though immediate improvement was noted. The acute conditions have afforded the most gratifying results, while in chronic diseases the response has been hard to evaluate. In the chronic cases the infections could be controlled and most of the wounds sterilized while the patients were receiving penicillin, but after treatment was terminated the infection again became active. In osteomyelitis penicillin has not supplanted surgical procedures but helps materially in combating the disease. Adequate drainage by surgical intervention in addition to penicillin was necessary to effect a cure in the majority of our cases.

Penicillin has proved equally effective against sulfonamide resistant organisms. All of our patients were given only penicillin, and none were treated by a combination of this drug and sulfonamides. Patients who had failed to respond to the sulfonamides improved under penicillin to the same degree as those that had not received sulfonamide therapy.

In this series of cases no toxic reactions to the drug either systemically or locally occurred. A few reactions such as hyperpyrexia and urticaria have occurred at our hospital, but except in a rare instance these have not constituted an indication for discontinuing treatment.

Penicillin was employed in the care of 7 cases of osteomyelitis, 5 involving the frontal bone, 1 the frontal and maxillary bones and 1 the superior maxilla. Three cases of orbital cellulitis secondary to sinusitis, 1 with osteomyelitis in addition, have also been treated.

In osteomyelitic infections granulations have been made healthy and draining purulent wounds have become sterile while the patients were receiving penicillin. It is now my feeling that the optimum time for operative measures in acute spreading osteomyelitis is during the period in which the infection has been checked by penicillin. However, it may well be that in certain acute cases if treated early and adequately the disease process may be stopped and healing will take place without radical surgical procedures. In the cases which continue to show progressive bone destruction after adequate therapy, surgical intervention may be accomplished with little risk after the wound has become dry and the cultures have become negative with healing of the surrounding cellulitis. It may require anywhere from one to two weeks of penicillin therapy to attain this state.

In chronic osteomyelitis of the frontal bone it is possible to obtain healing under penicillin therapy without resorting to extensive surgery, and a thorough trial of penicillin lasting over several months may be necessary. When there is no regression under this form of treatment it is my feeling that the involved sinus should be operated on and that this procedure in addition to penicillin therapy may prevent further extensive operations. The occurrence of exacerbations and failure of the disease to heal on discontinuing the drug may require removal of the entire frontal bone. Adequate, repeated and lengthy courses of penicillin treatment are believed to prevent this final step in some cases that might otherwise need radical intervention.

From the Ear, Nose and Throat Unit of the Surgical Service, Bushnell General Hospital, Brigham City, Utah.
Read in a symposium on "The Use of Penicillin in the Treatment of Diseases of the Eye, Ear, Nose and Throat" before the joint meeting of the Section on Ophthalmology and the Section on Laryngology, Otolaryngology and Rhinology at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 16, 1944.

One word of caution should be presented regarding the roentgen examinations, for these findings may indicate improvement and healing while treatment is being given yet at operation extensive necrosis has been found.

Brain abscess, extradural abscess and orbital cellulitis occurred as complications in 3 cases of osteomyelitis without apparent bearing on the response to the drug. The abscess of the frontal lobe of the brain was treated by the method outlined by King modified to the extent that a catheter was inserted into the cavity and local irrigations with penicillin carried out. The extradural abscess presented no particular problem, for the patient had been receiving adequate doses of penicillin and at operation the pus contained no organisms.

The longest period of treatment was that of the patient with osteomyelitis of the superior maxilla and frontal bones. He received 7,375,000 units of the drug over a period of sixty-six days. At the end of this time radical removal of the frontal bone was done because of the failure of penicillin to eradicate the infection permanently.

Our experience with other nose and throat diseases has been limited to a few cases of suppurative sinusitis treated both locally and systemically and several cases of peritonsillar and lateral pharyngeal abscesses in which the drug was given intramuscularly. The infections of the pharynx usually recovered without incision, but I do not recommend this method and I believe that healing would have followed more rapidly if drainage had been instituted. In a case of chronic purulent infection of the maxillary sinuses, cultures became sterile but the discharge continued and at operation the membrane was thickened with chronic inflammatory changes present. Acute infections of the maxillary sinuses have been cured after several irrigations with penicillin, even when the organism was a staphylococcus that had proved resistant to other forms of treatment. The strength of the solution employed locally was 250 units per cubic centimeter. Preliminary investigation of Vincent's infection of the mouth and tonsils indicates rapid healing, with disappearance of organisms after a few days of systemic penicillin therapy.

Complications of Paranasal Sinusitis Treated with Penicillin

Case	Complication	Organism	Treatment	Result
1	Osteomyelitis of maxilla	Strep. (nonhemolytic)	Incision and drainage; penicillin (general)	Recovery
2	Osteomyelitis of maxilla and frontal bone	Staph. aureus (hemolytic)	Penicillin (local and general); surgery	Recovery
3	Osteomyelitis of frontal bone; brain abscess	Staph. aureus (hemolytic)	Penicillin (local and general); surgery	Recovery
4	Osteomyelitis of frontal bone	Staph. aureus (nonhemolytic); Strep. (nonhemolytic)	Penicillin (general)	Unchanged
5	Osteomyelitis of frontal bone; orbital cellulitis	Staph. aureus (hemolytic)	Penicillin (general); surgery	Recovery
6	Osteomyelitis of frontal bone; epidural abscess	Strep. (nonhemolytic); Staph. albus (hemolytic)	Penicillin (local and general); surgery	Recovery
7	Orbital cellulitis	No culture	Penicillin (general)	Recovery
8	Osteomyelitis of frontal bone	No growth	Penicillin (local and general); surgery	Recovery
9	Orbital cellulitis	Strep. (hemolytic); Strep. (nonhemolytic); Staph. aureus	Penicillin (general); surgery	Recovery

Prompt and complete healing was obtained in 3 cases of orbital cellulitis with vanishing of pain within the first twelve hours of treatment. After the first day orbital edema, fixation and proptosis began to decrease, but the underlying disease in the sinuses remained unaffected and in 2 of the cases sinus surgery was essential. In the other case, during the early acute stage of cellulitis, before pus formation, incision and drainage were not necessary, the infection resolving under treatment. All of these patients had previously received sulfonamide therapy with little improvement.

One case of cavernous sinus thrombosis secondary to lateral sinus thrombosis and hemolytic streptococcus bacteremia was treated with the drug. Death occurred on the eleventh day of therapy, even though the initial response to penicillin was satisfactory and there was considerable improvement for a week. Daily blood cultures were positive only before penicillin was started and on the sixth day of therapy. In the first two days 400,000 units of penicillin was given by continuous intravenous drip, followed by 25,000 units intramuscularly every three hours thereafter. During the eleven days of treatment she received 2,335,000 units of the drug. At autopsy both lateral sinuses as well as both cavernous sinuses were thrombosed with an abscess of the cerebellopontine angle; so it is questionable whether surgical drainage would have altered the outcome.

I feel that at the present time penicillin in combination with adequate surgical treatment offers the most effective means of combating some of the serious and life endangering complications encountered in otolaryngology.

ABSTRACT OF DISCUSSION

ON PAPERS OF LIEUTENANT COLONEL KEYES, OF
CAPTAIN SWANSON AND LIEUTENANT BAKER
AND OF CAPTAIN PUTNEY

MAJOR ELMER A. VORISEK, M. C., A. U. S.: In the hands of my associates and myself penicillin has been used in a dilution of 500 units per cubic centimeter. In cases of gonorrheal ophthalmia it was instilled locally, four drops every hour with negative conjunctival smears and cultures after twenty-four hours, with no recurrences. Intramuscular injections were not given until after the ophthalmic infection was considered cured, except in 1 case in which the genital gonorrhea was cured with intramuscular injections, followed two days later by gonorrheal conjunctivitis in a previously enucleated eye socket. The smears and cultures were negative after twenty-four hours of hourly instillations. In our first case, in spite of rapid recovery within twenty-four hours, we continued instillations at three hour intervals for several days, and the patient developed a typical severe local allergic reaction. This reaction subsided quickly when instillations were discontinued. Even though negative smears and cultures of conjunctival scrapings may be obtained within twenty-four hours, the penicillin solution should be continued, but at less frequent intervals, until three such consecu-

tive daily examinations are reported as negative. We have also used penicillin to irrigate the lacrimal passages in cases of chronic suppurative dacryocystitis, 2 cc. of the 500 unit solution being used daily. After the second irrigation the secretion became almost negligible, and after several days only clear, amber colored, watery fluid was expressed on pressure over the sac. This led us to institute similar daily irrigations beginning within twenty-four hours after dacryocystorhinostomy, with excellent results. Several cases of orbital cellulitis with proptosis have been seen in conjunction with the otolaryngologist, but in each instance penicillin was used intramuscularly, and in 1 case the abscess also was irrigated with the penicillin. Not only did the cellulitis respond rapidly, but the purulent nasal discharge from all the sinuses promptly cleared up within forty-eight to seventy-two hours. In 1 case the low grade chronic sinusitis recurred. My associate has also been particularly enthusiastic in cases of osteomyelitis of the frontal bone secondary to suppurative, frontal sinus disease. There is every indication that, although intramuscular injections of penicillin were distinctly beneficial and were always used, the response, after periodic irrigations with penicillin, was immediate. However, it was found that even penicillin could not replace adequate surgical intervention and proper drainage. In 1 case, in which operation was performed before the advent of penicillin, the persistent drainage ceased immediately after local and intramuscular injection.

MAJOR WALTER J. AAGESEN, M. C., A. U. S.: It is our practice to give 25,000 units of penicillin intramuscularly every three hours day and night for twelve to fourteen days. Especially is this true when the offending organism is the staphylococcus. Captain Plough, in our department of bacteriology, has demonstrated that the sensitivity of different strains of staphylococcus to the action of penicillin varies considerably. He showed that the plasma level of patients receiving 25,000 units of penicillin every three hours intramuscularly does not reach a level of 1 unit per cubic centimeter, which is definitely below the concentration required to kill certain strains of *Staphylococcus aureus*. After testing twenty strains of *Staphylococcus aureus* for susceptibility to the drug, he has shown that the most sensitive strain was killed in a plasma concentration of 0.02 unit per cubic centimeter, while the more resistant organisms were not killed in a concentration of 2 units per cubic centimeter. Although at the end of three hours penicillin was readily recoverable in the urine, plasma studies have shown that after 25,000 units intramuscularly the usual plasma concentration during the first hour goes no higher than 1 unit per cubic centimeter. It drops rapidly during the second hour and is not recoverable in the third hour. There is still some doubt as to whether we are really able to shorten the convalescence of the average uncomplicated case of acute surgical mastoiditis appreciably. In chronic mastoiditis, and especially in the acute case with complications (such as meningitis, septicemia or Bezold's abscess), I feel that the convalescence is definitely shortened by the use of penicillin. It will not eliminate pus when there is inadequate drainage, and surgery is still of primary importance. We have found the drug to be effective in acute otitis media. Penicillin has produced a most gratifying response in chronic otitis. Three of our cases of long standing—from eighteen to twenty-five years—dried up completely, without healing of the perforation, in a period of from twelve to fourteen days, with a total of 2,000,000 units of intramuscular penicillin. It is still too early to state definitely that these cases will continue to remain dry. We have found that penicillin is of no value in chronic otitis media complicated by cholesteatoma or aural polypoid, except in 2 cases in which these conditions had been eradicated by surgery. Especially did we find this true when there was infection of the bone. The intravenous route, with its more even concentration, should be used until the infection has been brought under control, following which the intramuscular route can be substituted with maximum therapeutic effect. In bone infections, even though large doses were maintained in the acute cases, the results were disappointing as far as complete healing is concerned without the use of surgery.

COMMANDER E. E. KOEBBE (MC), U.S.N.R.: My associates and I have treated several hundred cases of early acute otitis media with penicillin, and the results have been universally good. We use 15,000 units every three hours around the clock for

about seven days or until the drum has resolved and the landmarks return. Then we reduce it to 10,000 and keep that up three or four days, then 5,000 for three or four days. We have treated 22 cases of meningitis complicating otitic infection. As soon as the diagnosis is established by lumbar puncture and by neurologic findings, we give 15,000 units intrathecally. We do not repeat that oftener than twenty-four hours. In most of the cases we give it intrathecally for two or three days until the patient becomes conscious or until the meningitis is under control. Supplementing the intrathecal treatment we give intramuscularly 15,000 units every three hours. We have given 20,000 or 25,000, but in most cases 15,000 units is adequate. The treatment in several instances cleared up the otitis media, so that no surgery was done on the mastoid. In most of the cases of suppurative mastoiditis the laboratory reported a sterile culture when treatment with penicillin was administered for three or four days. With penicillin, at first supplemented by the sulfonamides, recovery occurred in all otitic meningitis cases. Encephalitis cases respond well to intramuscular injections. We have treated 15 cases of lateral sinus thrombosis. In all there was a positive blood culture or occlusion of the lateral sinus demonstrated by operation or both. We give penicillin only intramuscularly at least twenty-four hours before operation, and in many cases the culture from the thrombosed sinus is sterile at operation and we have had no positive blood cultures on any one treated with penicillin for twenty-four hours. Penicillin alone is inadequate in treating lateral sinus thrombosis. An operation is necessary, but in no case have we ligated the jugular vein. We have had septic emboli occur before operation but none after operation.

CAPTAIN ROBERT HENNER, Barksdale Field, La.: I should like to call attention to the work of Schall in the use of heparin in venous thrombosis and tell of an instance of its combined use with penicillin in the case of cavernous sinus thrombosis. This patient was treated with sulfadiazine for about seventy-two hours and under this therapy became moribund and comatose and had a temperature of over 105 F. Institution of intravenous penicillin with the combined use of heparin in an intravenous solution caused the patient to develop rapidly a negative blood culture for the *Staphylococcus aureus* that was previously present, and in a period of over six weeks of recovery he was returned to full duty. We felt that penicillin offered the cure of disease only because the heparin was used in combination to provide local availability for the control of the infection.

CAPTAIN F. J. PUTNEY, M. C., A. U. S.: I should like to confirm the observation that lateral sinus thrombosis must be operated on as well as treated with penicillin. My associates and I have treated 8 cases of sinus thrombosis, and in every one the sinus was opened, but in a goodly number we were unable to remove the thrombus in the lower end of the sinus at the jugular bulb, and likewise in these cases we did not ligate the jugular vein. We gave adequate doses of penicillin, and, fortunately, did not secure any septic thrombi. Uneventful recoveries occurred.

CAPTAIN C. A. SWANSON (MC), U.S.N.: At the National Naval Medical Center, Bethesda, Md., the Penicillin Committee has now allowed us to use penicillin initially in acute otitis media in place of the sulfonamides. This should give us even better results. It was our experience in prepenicillin days that it takes mastoid wounds at least three weeks to heal. We have had only 3 cases in which penicillin was used locally in the mastoid wound and all 3 cases were healed in eight days. The Floreys in England are the investigators that first advocated the method I have described of controlled drainage. Their surgeon reported 19 out of 22 cases of primary healing in mastoid wounds.

LIEUTENANT COLONEL JOHN E. L. KEYES, M. C., A. U. S.: Those of us in the armed services have had opportunities to study penicillin that were not available to our colleagues at home; therefore it seems only proper and right that we should pass on to them at this stage, when penicillin is becoming available to them, the result of our studies so that they may now join us in further study of the usefulness and limitations of this drug.

SULFONAMIDE THERAPY OF
GONORRHEARESULTS IN 555 WOMEN MAINTAINED AT A
VENEREAL DISEASE TREATMENT CENTER

RUTH BORING THOMAS, M.D.

WILLIAM E. GRAHAM, M.D.

AND

GEORGE R. CANNEFAX

Surgeon (R), Senior Surgeon and Assistant Bacteriologist, Respectively,
United States Public Health Service

HOT SPRINGS, ARK.

Although the number of gonococcal infections in women which have been treated with sulfonamides may run into the millions, there are few reports of results in groups of patients under good enough behavior and treatment control to make them a reasonable substitute for the laboratory animal whose lack has impeded study of this infection. The present material is therefore an example of what can be achieved in a group of women, domiciled throughout in an institution where therapeutic efforts are directed toward improving their clinical condition and enabling them to pass bacteriologic tests of cure as early as possible, and where no patient is released as presumably cured until she can pass such tests. It is derived from the case records of 555 women, 200 Negro and 355 white, who were treated for culture positive gonorrhea at the U. S. Public Health Service Medical Center, Hot Springs, Ark., from December 1942 to April 1944. The mean age of this group is about 20, but a large number are still in their teens. Many types are represented, ranging from young school girls to professional prostitutes. Some are drawn from a wide area, although the greater part come from Arkansas and the adjoining states. The notably high incidence of a precarious family background is reflected in the unstable lives of these women. This background contributes its share toward their many brief marriages, lightly undertaken and soon terminated, and their uninhibited sexual behavior, whether married or single. The social unrest attendant on the war has played its part in their lives as well. Many come from small towns and villages, this being a predominantly rural state, and many have been apprehended in the vicinity of large military establishments, where they have migrated, to work sometimes as food handlers or in other poorly paid positions and consort with the soldiers for extra earnings and for pleasure. About three fourths of the total number are committed under the state quarantine regulations, which prescribe that they shall be held for treatment until noninfectious.

The admission history, which includes questions as to symptoms of gonorrhea, state of health of contacts and previous treatment, is often of very uncertain value from an epidemiologic standpoint or as an aid in establishing the diagnosis. A large proportion of the women are unaware of their infection until medical examination reveals it, and few give a history of symptoms. The most common complaints are lower abdominal pain and a vaginal discharge, though the latter complaint occurs as frequently in the nongonorrheal as in the gonorrheal patients. The incidence of clinically detectable pelvic changes is higher in these patients than the symptomatic history would lead one to expect. It has been our experience that a clinical diagnosis is of uncertain value and that the presence or absence of clinically recognizable urethritis or cervicitis, particularly in the chronic

infections, bears only a partial relation to the bacteriologic findings. Cervicitis and vaginitis from other causes are frequently encountered. This finding, in conjunction with the vague histories, often makes it impossible to date the onset of gonococcal infection or to determine its present stage. However, few of the infections in this group were considered acute.

On admission each patient received a physical examination, and a spread and culture were taken from both urethra and cervix. Cultures were taken from Bartholin's glands or rectum only in the presence of clinical changes warranting suspicion of infection. Appropriate tests for other venereal diseases, complete blood counts and urinalyses were performed. Bacteriologic tests for gonococci were repeated every other day, if negative, until a total of six had been taken, without interruption for the occurrence of a menstrual period. Indeed, through much of the study an effort was made to take at least one culture during a menstrual period, but experience has not shown this procedure to have great diagnostic value. After treatment and after six negative spreads and cultures performed over a two week period the gynecologic condition of each patient was determined by examination and, if a frank urethritis or vaginitis was still present, an attempt was made to clear this up by local therapy. Treatment was not continued, however, until all clinical signs of cervicitis had disappeared, partly because in our experience these have little relation to the bacteriologic findings but chiefly because in a rapid treatment program such a long observation period is not feasible. For the same reason, although no patients with acute or subacute pelvic inflammatory disease were released, some were discharged in whom the residual signs of such a process persisted.

After careful cleaning of the site, removing the mucous plug and massaging the cervix, cultures were made by streaking the secretions on the surface of the medium. The medium used was proteose number 3 agar and hemoglobin (Difco) fortified with glucose to make a final concentration of 0.2 per cent; 1:800,000 crystal violet and 5 mg. of para-aminobenzoic acid per hundred cubic centimeters. Glutamine¹ and liver extract growth accessory substances were added as suggested by Lankford.² Only a short time elapsed between the taking of the cultures and their incubation, which was in an atmosphere of about 10 per cent carbon dioxide at a temperature of 35 C. After forty-eight hours the cultures were inspected and were sprayed with para-aminodimethylaniline monohydrochloride, and those colonies which showed a positive oxidase reaction were stained with Gram stain and examined under the microscope. Carbohydrate fermentations were done only in exceptional cases.

In the group under consideration, treatment was never instituted except on demonstration of gonococci by culture at least once. In many instances gram negative intracellular diplococci were also found in the spreads. Every patient was treated with sulfonamides, even when there was a history of recent similar treatment. If the latter was given in the same type of institution as this center, it was considered in determining sulfonamide resistance in a few of the patients treated subsequently with penicillin. All results reported in the sulfonamide group, however, were obtained by

ourselves. Each dose of medication was ingested under the supervision of a responsible member of our personnel. Most patients received sulfathiazole in either of two systems: 1 Gm. four times daily for five days or 2 Gm. four times daily for two days and then 4 Gm. daily for three days. In some instances sulfadiazine was substituted in the same dosage, but in our experi-

* Second course not given to 16 failures after one course.

ence it was no better than sulfathiazole. We adopted the larger dosage schedule to compare it with that so generally used, 20 Gm. in five days. At first it appeared to produce more cures, but later experience did not bear out this impression and it was dropped because of the higher incidence of reactions. A period of five days elapsed between completion of a drug course and the taking of the first test of cure. If the culture was still positive and the white blood cell count not unduly depressed, a second course was given of either the same or the alternate drug. If this failed, the patient was considered sulfonamide resistant. In a few instances a third course was given alone, but usually there was recourse to other measures, such as combining a sulfonamide with nonspecific protein therapy. This consisted of a series of intravenous injections of enough typhoid bacilli to produce a moderate, febrile reaction every other day for five days. About one third of the patients thus treated became culture negative. If one focus of infection was found which could be eradicated, this was attempted, but often with indifferent results, particularly in the cervix, where deep cauterizations were not undertaken. When other measures failed, artificial fever, eight to ten hours, at 106.6 F., with 6 Gm. of sulfathiazole administered during the preceding eighteen hours was used for 25 patients, with twenty-three known successes. After penicillin became available it was used in preference to other measures. In this series 10,000 units was injected intramuscularly every three hours for a total of 60,000 units. Failures were retreated with 20,000 units every three hours for a total of 120,000 units.

Part way through this study it became apparent that many of the maneuvers required to rid the white women of their gonococci were unnecessary in the Negroes. All the patients receiving artificial fever were white, as were all but 1 of those for whom penicillin was used. When case records were grouped on a racial basis the statistical differences shown in table 1 emerged.

Obviously, if such divergent results are shown to be the rule, any estimate of the effectiveness of a dosage

schedule or amount of sulfonamide treatment must take into account the proportion and distribution of the racial components in the group under consideration. Thus the total cures for the whole group of 555 sulfonamide treated women, shown in table 2, would have been higher if the proportion of Negro to white had been reversed.

The initial advantage which the "intensive" sulfathiazole treatment scheme seemed to have over the "routine" may also be explained on a racial basis, since patients were treated just as they came and no racial differentiation was made in the tabulation of the early results. As shown in table 3, when this differentiation is made there is no statistically significant difference between the final results produced by these two methods.

This study includes, as well, 50 white women whose infection proved resistant to at least two courses, or a total of 40 Gm., of sulfonamide and who were treated with 60,000 units of penicillin. The results are shown in table 4.

Since the majority of patients were asymptomatic on admission, their reaction in this respect was no measure of the effectiveness of therapy. Some noticed a decrease in the amount of vaginal discharge. In others this remained unchanged, particularly in the presence of chronic cervicitis or nonspecific vaginitis, even though the gonococcus could no longer be recovered from the secretions. It may be noted, incidentally, that when vaginitis is associated with the presence of *Trichomonas vaginalis* the removal of clinical signs of this infection through treatment does not affect favorably the course of a gonococcal infection or make it easier to cure. Local treatment of the cervix by injection of a concentrated aqueous suspension of microcrystals of sulfathiazole with a fine needle directly into the cervical tissue, in a ring parallel to the cervical canal, failed in all of 5 cases.

In some complications of the adnexa and Bartholin's glands, sulfonamides failed to produce improvement.

Dosage	Cure		Failure	
	No.	%	No.	%
10,000 units every 3 hours for a total of 60,000	47	94	3	6

A larger number were improved clinically and symptomatically though still retaining gonococci in the cervix or urethra. Many patients with such complications were cured both clinically and bacteriologically. Chronic purulent infection of the urethra and paraurethral glands were apt to persist after gonococci could no longer be found by culture or spread. The patients themselves were practically never aware of such infections.

Reactions to sulfonamides were few and usually mild. In a number of instances sulfonamide therapy could

be completed by changing from one compound to another. Four instances of conjunctivitis occurred, usually after completion of the course. The only serious reactions were 3 instances of ureteral blocking; all occurred in patients on the intensive dosage, relatively early in the course and during very hot weather. After precautions were adopted to maintain an adequate fluid output, no more were seen. Early hematuria necessitated stopping the drug in 3 other patients.

COMMENT

In spite of the impression, so long and so generally held, that gonorrhea in women is more difficult to cure than in men, the figures here presented indicate that under controlled conditions this is not the case. Our results are strikingly parallel to those reported by Turner and Sternberg³ for the Army, both in the series as a whole and in the separate racial groups. Their figures and the recent discussion by Pelouze⁴ emphasize and support an impression apparently held by some Southern clinicians for a long time, that gonorrhea in the Negro was easier to cure than in the white person. No explanation of this difference, the reality of which now seems well established, is offered. Whether it is due to the infection of Negroes in general with strains of gonococci more susceptible to the action of sulfonamides than those found in white patients, or whether there is a higher racial immunity, cannot be decided without more evidence than we now have. If strain susceptibility is the reason, a reduction of the proportion of cures that can be obtained in Negroes with sulfonamides may be expected as the more susceptible strains die off, acquire sulfonamide resistance through exposure to sublethal concentrations of the compounds or are replaced by strains already resistant. If racial immunity is the explanation, its importance in problems of treatment and control is evident. Two important questions deserve further study, namely, whether the superiority of results with sulfonamides in Negroes will be maintained and whether the Negro race will respond relatively as much better to other treatment measures. At any rate, since much can be accomplished with the sulfonamides in women, Negro or white, they remain a useful therapeutic weapon, though not the most effective that has been or will be developed.

SUMMARY

1. Results of sulfonamide therapy, chiefly sulfathiazole, in 555 culture positive gonococcal infections in institutionalized women, are as follows: In 200 Negro women 90 per cent passed the tests of cure after one course of treatment and 95 per cent after two courses. In 355 white women 60 per cent passed tests of cure after one course of treatment and 70 per cent after two courses.

2. These results correspond closely to those recently reported with both Negro and white men in the Army.³

3. The evidence presented here indicates that under controlled conditions the bacteriologic cure of gonorrhea with sulfonamide compounds is as readily brought about in women as in men. This is true also for penicillin.

4. An explanation of the difference in response to sulfonamide therapy between Negro and white patients, must await the results of further investigation.

WARTIME EXPERIENCES IN HAWAII
AFTER THE BLITZ ON
PEARL HARBOR

F. J. PINKERTON, M.D.
HONOLULU, HAWAII

In Hawaii, as in the rest of the world, the average person does not consider public health to be one's business; only when a major epidemic or disaster threatens does one become interested in, helpful to and critical of the local health board. Let the threatened calamity be brought under control, and Mr. and Mrs. Average Citizen again relax and become involved in more personal interests.

The definition of "public health" should be self explanatory in that it is health for, by and of the people and this simple fact should and must be recognized by people generally in communities throughout America—yes, throughout the world. Public health cannot be left to the public health services or to the professional worker alone, for it is the business of each one of us. It must be part of an overall community plan, as is fire protection or police protection. Laws must be enacted and violations must be punished. Public opinion must be aroused, and not only the medical men but every citizen must take an active interest. The interest of boys and girls at school, of the churches, of the employer and the employee must be aroused, and the newspaper and radio must carry the banner under the leadership of the local health agencies, both public and private. Let it be fashionable or profitable to be healthy, and a good start will have been made.

The local health official, frequently operating with an inadequate staff, finds himself limited in the extent to which he feels able to go without public interest behind him. To get this he needs the help of volunteers. He needs community backing. Such a project as this might very well engage the attention and active participation of all the chambers of commerce in communities throughout America. It is important, it is interesting, it is profitable. Healthful communities are fine communities in which to live and work. It pays dividends not only through happier lives but also by reducing loss of man hours.

Notable among the worthwhile achievements concerning public health in the Territory for the past many years has been the work of the public health committee of the chamber of commerce. I have been chairman of this committee for the past eight years and as such have at all times tried to promote the best interests of the medical profession in its relation to the health and welfare of the community. Having served in key positions with the medical societies over the past twenty-five years, as well as having managed the blood bank for the past three years, I have come to the conclusion that medical men individually, and all too frequently, collectively have shown an abysmal lack of interest and concern over the health affairs of their community. Our public health committee has more than adequate finances and has promoted such major projects as health legislation, mental hygiene, reorganization of the leprosy program, dengue fever control, poliomyelitis control, mosquito and parasite control, plague control, tuberculosis surveys, the original prewar blood bank and numerous other investigations and studies of major or minor importance to the extent that more than a million dollars has been expended by

the chamber of commerce health fund over the past several years in the interest of making Hawaii a better place in which to live.

The members of the medical profession have gradually come to accept and to appreciate the success of many of these projects, though at intervals in the past there has been keen opposition by them to some of the things which the members of the public health committee were endeavoring to do.

Our public health committee of the chamber is a unique organization in that no other organization, to my knowledge, has such funds. During the great plague epidemic in 1900, at which time a large part of the city of Honolulu was destroyed by fire, the shippers inaugurated a system of collecting a voluntary tonnage contribution of varied amounts from all persons receiving freight across the wharves in Honolulu. This procedure had the sanction of the courts and has been continued. This income, amounting to as much as \$100,000 in one year, has been available to the chamber of commerce through its health committee to expend for health improvement in the Territory, chiefly in the city and county of Honolulu, so that our community is in a position to finance immediately any project which suddenly requires attention, such as an epidemic or disaster, ordinarily taken care of by taxpayers' funds but which would ordinarily not be available without slow and unwieldy special legislation. The members of this committee have full power to act and are subject to no regulation other than public opinion.

SHORTCOMINGS OF MILITARY RULE

A powerful influence on both the public and the private health of Hawaii and its peoples has been martial law and the blackout. On the day of the blitz, Dec. 7, 1941, one of the first official acts of the governor was to declare martial law for the Territory. This was done before noon on December 7. Since that time there has been much controversy and no small amount of ill will created between the military and the civilian population regarding certain phases of the regulations. I think it is generally agreed that the civilians of the Territory were entirely favorable to the institution of martial law in the early days following the blitz. I wonder how many realize just what such a drastic regulation means to the way of life of any civilian who has not been accustomed to such regimentation. It means, in short, that everything a civilian does and says is subject to regulation by the military authorities. We in Hawaii have learned from experience that the military authorities fall far short in their understanding of proper methods to administer the purely civilian affairs of a community. While it is admitted that such drastic measures were necessary, it is also generally agreed that the methods of carrying out the necessary regulations were, many times, unnecessarily drastic and unreasonable. This naturally results when military officer executives are appointed who had had no experience with martial law on such a large scale nor any background or knowledge of the problems peculiar to that community. It is something that one is sorry to have endured, even though the experience probably has been valuable. One certainly becomes appreciative of its modifications.

All are no doubt familiar with the litigation relative to the operations of the provost court and the suspension of habeas corpus in Hawaii. Our experience with military rule convinces the large majority of us that

a commission form of government is not desirable for the people as a whole. On the contrary, our experience is the best recommendation for a continued form of democratic government. This must not be construed as a criticism of the military during the trying days after December 7. Those were critical times, and prompt and drastic action was required. There was not only the fear of attack from without but also the fear and uncertainty of attack from within, considering that we have in the Territory approximately 163,000 Japanese, 35,000 of whom are aliens and 64,000 of whom have been catalogued as enjoying dual citizenship.

One can readily understand how grave the situation might have been. Yet there has been little evidence of sabotage or organized effort to thwart the authorities in Hawaii. Immediately after war was declared on Japan the Army and Navy Intelligence, in cooperation with our own local police force and the Federal Bureau of Investigation, rounded up not only the Japanese but others as well who were known to have subversive leanings. Large numbers of these people were incarcerated as internees and subjected to a complete and thorough examination. Those found undesirable were sent either to the mainland for location in internment camps or to internment camps in the Territory. I think it is safe to say that every citizen in the Territory, regardless of racial descent, has some sort of an FBI record in the files. Some, of course, have been investigated much more critically and completely than others—and the constant fear of investigation and subjugation caused a high percentage of apprehension and mass depression.

Immediately after December 7, under orders of the military governor, every person in the Territory, from the oldest to the youngest, was compelled to have a certificate of identification issued after a comprehensive examination, including fingerprinting. Regulations made it mandatory that at all times, day or night, an identification card must be in the possession of the individual to whom it was issued. Every one—and I do mean every one—with a few exceptions was vaccinated for smallpox and given a series of typhoid injections early in 1942 by military order. Booster shots for typhoid before June 15, 1944 have now been ordered by the civil government.

INCONVENIENCES OF THE BLACKOUT

The blackout has probably been the greatest objectionable feature, because during the winter months the total blackout regulations for the Islands started at sundown, which is in the vicinity of 6 o'clock, and lasted until as late as 7:15 in the morning. This meant that all houses had to be blacked out, and when I say blacked out I mean thoroughly and completely, because there was always a guard to see that one did not have even a slight crack of light showing from the premises. If any light showed there was often no warning; one was taken to the police station and the provost judge imposed a fine from \$25 up, depending on his disposition at the moment. The second or third offense meant a stiff fine, and in many instances jail sentences were imposed. The blackout in the Territory was total and complete. This, of course, was a great hardship on people of the poorer class, because their houses were not built for such arrangements and during the hot nights people would sit in one small blacked out room sweltering from the heat and lack of ventilation.

Strangely, this did not, according to our public health records, increase our upper respiratory health conditions materially—a thing we could not understand, although we feel that it has been a contributing factor to the increase in cases of tuberculosis. It did, however, produce an increased amount of mental illness and morbidity in that direction. There were several reasons for the enforcement of such a drastic rule: the fear of attack by airplanes or ships at sea; such a regulation completely prohibited people from gathering in groups; it saved electric power urgently needed in defense projects. No one could be on the street after blackout except those engaged in essential operations, and they had to be in possession of a pass which gave them this privilege. Under no conditions were aliens ever permitted on the streets after blackout.

Gradually this regulation has been modified to the point where the curfew begins at 10 o'clock, and for the past month we have been permitted to leave our light on all night if we so desire. We are grateful for this privilege, and most of us subscribe to the argument that the blackout was probably a good thing in spite of the personal inconvenience it caused.

MENTAL HYGIENE

The physical health of any community is influenced by the mental health of its members, and this has been amply demonstrated in Hawaii since the war.

Some of our leading internists have this to say about internal upsets: "We are finding a great many more cases of general gastric and intestinal irritability, associated with much evidence of vascular instability, shown by swelling of the stomach and the intestinal or gastrointestinal membrane as shown by x-rays. This condition we have also found will be frequently associated with ulcer symptoms and frequently superficial ulceration which may go into deeper ulceration. The picture is variable. Quite sizable ulcers frequently disappear in the course of a few weeks, apparently recurring with increased mental worry or fretting over abnormal conditions. There are definitely ten times as many of these cases since the war. War and abnormal conditions have had a definite effect. Patients respond to treatment and rest."

It is suggested from our experience in Hawaii that there is more and more to the theory of an acute allergic phenomenon resulting from or associated with conditions of life which increase nerve tension. It is an interesting observation that when a patient is removed from the environment of extreme nervous tension many of his allergic symptoms disappear completely.

One large group of problems is that which includes the problems connected with the uncontrolled, promiscuous employment of women who are the mothers of many small children. At the same time we have been receiving impressive documents from Washington entitled "The Children's Charter," setting forth all the precautions to be taken to insure proper mental health for children in wartime. We see our local federal agencies employing the mothers of as many as eight children, which children are then turned loose on the community without supervision, and no children's organization had or was provided with the facilities for their care. A great deal of the damage to children resultant on this kind of occurrence is not shown in the juvenile delinquency statistics.

Another contributing factor has been the war workers brought here from the mainland. The recruiting program for these workers has been so handled as to

provide practically no consideration of the individual's history or ability to adjust to conditions here. A large number of emotionally immature persons have been brought to Hawaii, and they have not got along well. A number of psychopathic personalities, alcoholic addicts, feeble-minded persons and even psychotic individuals have been brought here by the federal agencies. The adverse conditions under which these war workers live contributed to the mental hygiene problem of this group.

Bad thinking on the part of the military and the local civilian government with regard to providing housing conditions for 75,000 people is responsible for the thousands who are living in tents, shacks and holes in the wall.

We are told that Honolulu is the most crowded city in the whole United States. It is quite as important to provide shelter for the civilian population as it is for the service personnel. Housing facilities for the civilians are woefully lacking in Honolulu.

It has been estimated by qualified observers that in Hawaii, just as it is reported to exist throughout the mainland, there is a very high percentage of inefficiency of voluntary war work among the civilian population.

PREPONDERANCE OF MEN

There is a general attitude of taking advantage of the benefits made possible by the war. I speak especially of the so-called volunteer workers. The great preponderance of the male population in our Territory is well known. Quoting from one of our best authorities, one does not have to look far to note the unhealthy effects of this on the women as well as on some of the men. This is not confined to young women; the woman over 35 has come into almost a second youth as far as masculine attention is concerned. The woman who has considered herself settled as a "wife and mother" has become socially more desirable and economically independent. When some women are suddenly given increased social status, desirability, importance and contacts always considered unavailable to her, it is not unusual to find her showing a new independence and lack of cooperativeness at home and at work. As far as the women are concerned, there seems to be a keen rivalry among the varied organizations requiring the wearing of a natty uniform. Private surveys involving thousands of men in the armed services indicate that only about 6 per cent of them demand female companionship, while 42 per cent want more sports facilities, 40 per cent want more movies and other small groups want art, photography or music. The demand by this small percentage of the overwhelming male populace for the companionship of women very easily throws otherwise stable individuals into a state of self aggrandizement and makes their contribution to the war effort secondary to their personal ambitions, which they subscribe to under the guise of patriotism and with the license that goes with it. It therefore appears that a tremendous amount of woman manpower effort is being expended for an insignificant number of men in uniform—far in excess of rational and reasonable requirements and to the detriment of many other less alluring activities.

My remarks should be modified with respect to certain volunteers, both men and women, who are doing their jobs well, and against whom no criticism should be leveled. However, if the social life that they are engaged in extracurricularly is so demanding and excessive as to render them inefficient in their full time

occupations, then the influence of the war in Hawaii has been definitely disastrous. I have a great respect and admiration for those women who are economically independent, who serve so efficiently and well in the various hospitals as nurses' aides. Many features of such work are distinctly undesirable and distasteful to women of this class, yet we find them putting in their capacity hours each day of the week and rendering an invaluable aid to the various institutions. People engaged in such activities do not need a brass band or self declaration to tell of their contribution to the war effort, because their efforts are measured and recorded by the agency to which they are assigned. We call this type of service in Hawaii measured and measurable patriotism. There are many other organizations, connected and not connected with hospitals, doing equally superior work.

Owing to the preponderance of the male population and to the fact that many men are in Hawaii without their families and are lonely and eager for companionship, with plenty of money to spend, too often the wife has found release from a humdrum existence with a suddenly uncongenial husband and left her home and family for an adventure that is happier for the moment with a mainland war worker or a member of the armed forces. She is entertained and amused and she enjoys it thoroughly. The fact that such a relationship is temporary as well as immoral doesn't seem to matter. Naturally her actions and attitude have a profound effect not only on her children but on her friends and the community. She may think that she is "getting away with it" until the great awakening.

DIFFICULTIES OF READJUSTMENT AFTER EXILE

The thousands of local citizens who were practically forced to leave the Territory during the early days of the blitz are gradually returning to Hawaii at the pleasure and will of the Army and Navy. This has been probably one of the greatest disrupting factors, but this disastrous state is gradually being corrected. Many men who sent their wives and children away soon after the blitz, with the best of motives, have found adjustments difficult to make with the long last returning of their wives and families.

EPIDEMICS

The tremendous number of defense workers and Army and Navy personnel which has flooded Honolulu has brought to our acute attention the grave problem of venereal disease control. Fortunately our local board of health has splendid cooperation with the health departments of both the armed services. Otherwise our excellent record could not have been achieved and maintained.

For many years Hawaii has had lower than average venereal disease rates. Long before the onset of the war, board of health regulations were issued which made it obligatory to report all new cases of venereal disease—civilian, Army or Navy—to the health department within twenty-four hours after diagnosis, along with information as to the suspected sources of the disease. Since the blitz a military order has been issued along the same lines. The health department assumes the function of investigating such suspected sources.

To prevent infection among the armed services, educational activities were sharply accelerated. Hundreds of thousands of pamphlets were provided by the health department for distribution to service men. Adequate

prophylactic facilities were provided by the Army and Navy and made available to civilians.

Along with efforts to reduce the incidence of disease in the many thousands of soldiers and sailors stationed in and advancing through Hawaii, case finding and educational activities for the civilian community have also been augmented.

Since the summer of 1942 there has been a decided increase in public interest concerning venereal diseases. Newspapers have devoted considerable news space and some editorials on the subject, and all radio stations in the Territory have provided free time for the release of venereal disease broadcasts. This change of public attitude was reflected in the passing of the Prenatal Blood Test Law by the 1943 session of the legislature.

In cooperation with the Department of Public Instruction, classroom teaching about the venereal diseases has been instituted in the high schools. As far as possible this instruction is integrated with that concerning other communicable diseases. There has been a compulsory chest x-ray examination of all food handlers. A Wassermann test has been done at the same time in an effort to promote the control of venereal diseases.

Incidence of tuberculosis deaths in 1940 was 63 per hundred thousand, based on a population of 426,654. In 1943 this had dropped to 56 per hundred thousand, based on an estimated population of slightly more than one-half million. This indicates that the effect of the war on the incidence of tuberculosis deaths has not been adverse.

However, there is a definite increase in the number of tuberculosis patients in the Territory. It is estimated that in 1940 there were 1,474, whereas in 1943 this had increased to 1,949. The patients hospitalized in sanatoriums throughout the Territory were 860 in 1940 as against 1,063 in 1943.

Contributing factors of the increase are, of course, increased population and the large numbers of defense workers, the majority of whom had totally inadequate physical examinations. The majority of these people are located in and around Honolulu. There was also a large migration from the outside islands to Honolulu for war work. Overcrowding is probably the greatest single factor in this increased incidence of tuberculosis. The stress of modern living, prolonged physical and emotional fatigue, overcrowding, poor ventilation resulting from blackout restrictions, bad eating habits, lack of recreational facilities and overindulgence in alcohol greatly contributed to the increased number of cases of tuberculosis. Though an improved system of case finding has been adopted by the board of health, it is generally considered that this has not been the sole reason why so many new cases have been discovered.

Forty-three thousand 4 by 5 inch films have been taken since 1942, the majority of these being of the draftees and the food handlers, who by law are compelled to submit to a chest x-ray examination. In Hawaii 2 per cent of our draftees presented x-ray evidence of tuberculosis, as did 3.5 per cent of the food handlers. It is estimated that there is a bed shortage for cases of tuberculosis in the Territory of approximately 1,000. Honolulu at the present time seriously needs from 400 to 500 additional tuberculosis beds. But if we had these additional beds we would not be able to supply personnel sufficient to care for the patients, as all of our formerly available help are now engaged in war work at fantastic salaries, and more glamor and excitement are attached to these war positions.

The following observation is interesting and has a direct bearing on the increased demand for medical care: An analysis of the statistics from our community clinic indicates that since 1939 the number of charity patients visiting this clinic has diminished more than 60 per cent, though the cost of each individual visit is exactly double in 1943 what it was in 1939. In 1939 it cost us 78 cents per visit for 72,169 visits, while in 1943 it cost us \$1.57 each for 34,591 visits.

A dengue fever epidemic began in the Waikiki district in the early part of 1943. The total number of cases, exclusive of the military cases, was 1,485 as of May 3, 1944. Assisted by specially trained corpsmen of the U. S. Army, two hundred persons are constantly at work in the control of dengue.

An epidemic of poliomyelitis started early in 1943, and an emergency hospital was set up originally by the Office of Civilian Defense in April 1943 on the ground of the Shriners Hospital, when there were 58 patients. On Sept. 1, 1943 the Emergency Poliomyelitis Hospital was formally taken over by the Aloha Temple of the Shrine and conducted as a separate institution from funds of more than \$200,000 donated by the public for the emergency. To date 100 patients have been admitted, the average daily cost per patient being \$17.25. The epidemic soon abated and at the present time there are but 4 active cases.

THE BLOOD BANK

So much has been said about the part played by the Civilian Blood and Plasma Bank at the time of the blitz that further information may be desired concerning the operation of the blood bank since that time. This bank was in operation for almost a year before the blitz.

One of our aims, when we could gather our forces together after the blitz, was to determine the blood type of every resident in Hawaii. We have fallen far short of that aim but are pleased to report that approximately 250,000 blood typings have been done. Our statistics clearly demonstrate that race influences the blood type of an individual, although we cannot determine race by blood. International averages show 43 per cent O, 40 per cent A, 12 per cent B and 5 per cent AB. Our percentages follow quite consistently, 36 per cent O, 39 per cent A, 18 per cent B and 7 per cent AB.

Owing to the blackout conditions and the military order forbidding citizens to be on the streets during the blackout hours, Honolulu was faced with the difficulty of providing emergency blood transfusions. So immediately after the blitz the blood bank, operating then under the direction and control of the Office of Civilian Defense, instituted a whole blood and plasma transfusion service readily available to all the hospitals in and near the city. At our main blood bank on the Queen's Hospital grounds, donors were received, and after all the necessary laboratory work was done on the bloods they were then distributed to the various hospitals to be kept under refrigeration pending their need. This was a godsend to the people of Hawaii. Out of that emergency need we developed a lend-lease plan whereby blood from our central stores could be used at any time on any and all patients and in such quantities as were required, the only condition being that this blood be replaced by a friend or member of the patient's family, who was required to give his blood at the central bank. To date, approximately 30,000 donors have been received at the Honolulu Blood and

Plasma Bank. The excess of blood that is not used for whole blood transfusion is returned to the central bank within seventy-two hours and processed into plasma.

On Oct. 1, 1943 the operation of the blood bank under the Office of Civilian Defense was turned over to a board of directors of an organization chartered by the Territory, and it has been maintained since that time on an independent self-supporting basis. We have enjoyed excellent cooperation from the Army and Navy medical departments. Approximately one half of our donors come from the people in the armed services, who, of all people, have come to appreciate the importance of plasma and blood transfusions. No charge is made to the armed services for the use of blood or plasma. We give to the various hospital units and the ships at sea as much blood and plasma as they ask for, without charge and without red tape. Our budget per month runs in the vicinity of \$5,000. This money is raised from service charges of \$5 per dose of blood and \$10 per dose of plasma, when the amount borrowed is replaced; and from direct charges to patients who are unwilling or unable to send in donors to replace the blood or plasma used, at the rate of \$20 per dose for blood and \$25 per dose for plasma. In these lucrative times, when every one has money, we have been faced with the situation on several occasions when we had more money than blood. People often prefer to pay us as much as \$300 for blood that has been used in an especially severe case than to send in, say, fifteen donors to replace it. On several occasions we have been compelled to use prison donors; whom we pay \$10 for each donation. This is done only when our supply of donors runs short because of cash payments. In order to have a cash reserve for emergency needs, as director of the blood bank I made a personal appeal to a few prominent business corporation heads, and within three days \$20,000 was donated, which we are using as a revolving fund on a reserve basis.

An interesting observation has been made with regard to the percentage of serologic tests done on all donors since the beginning of our bank. In the first year of operation more than 5 per cent of our donors showed a positive Kahn or Wassermann reaction. When such a report is found, in cooperation with the board of health, measures are immediately taken to put the patient under treatment, and, of course, he does not return to the blood bank again because we have advised him that his blood is unsuitable, but we have accomplished a great public health benefit as a case finding agency among a large number of people, who perhaps were ignorant of the fact that they had a syphilitic infection. With each succeeding year, since our early days, there has been a noticeable drop in the percentage of positive Wassermann and Kahn reactions. Since December 1942 we have used the Kline exclusion test on all donors, and only those bloods which are Kline negative are used for whole bloods. Doubtful and positive Klines are checked by the Kahn standard test, and those bloods which are negative Kahn are used for plasma.

We have built up a reserve of plasma to be used at a time of disaster, such as another blitz, and the Peacetime Blood and Plasma Bank, which has existed since Oct. 1, 1943, has accumulated a considerable reserve of plasma for local and emergency needs.

The blood bank has been responsible for making anti-Rh serum available to all service and civilian hos-

pitals. The blood bank has itself done Rh testing on some 1,500 donors and has developed a register of Rh negative donors of all four blood types. In this connection it is interesting to note that the percentage of Rh negative persons among Caucasians is the same as that found by the Certified Blood Donors Service, i. e. 15 per cent, but so far we have found only one Oriental who is Rh negative, and not any Filipino or Hawaiian-Oriental who is Rh negative.

The blood bank has sponsored the use of specific substances A and B, developed by Witebsky and his associates. Ten cc. of these substances is added to type O blood so that it can be given in emergencies when the patient's type is unknown, without cross matching. We have also found that "treated O," as we call this blood when the substances are added, can be used for specific type patients without reaction and, in fact, to advantage when it is difficult to secure a compatible blood in subgroup patients. We are now using more than 50 "treated O" bloods per month, out of a total of approximately 400 bloods per month.

PROCUREMENT AND ASSIGNMENT

Since my appointment as chairman of the board of Procurement and Assignment Service for Physicians for the Territory of Hawaii we have met once each week for the purpose of determining the availability of physicians for military service or their essentiality to the community. One major conclusion should be mentioned. The board of the Procurement and Assignment Service feels unanimously that its responsibility in keeping a man out of the service if he desires to go in is even graver than it is in making him available for military service and forcing him into the Army or Navy when he does not want to go.

The geographic location, the varied races involved and the new people that are constantly coming to Hawaii on defense projects have made our problem in Hawaii particularly and peculiarly difficult. The facts that a large percentage of our population is of Japanese ancestry and that 30 per cent of the physicians of the Territory are of Japanese ancestry have made our problem in this regard unique. Since Japan is our enemy, it is understandable that the Army and Navy are rather loath to accept commissioned officers of Japanese ancestry, even though they may be American born and have good records. On the other hand, the board of the Procurement and Assignment Service is confronted with this great dilemma: If the Japanese physicians are not acceptable to either of the armed services, and if our percentage quota of doctors per thousand of population is such that we can spare medical men for the services, then the ratio of doctors per thousand for the various racial groups will be thrown entirely out of balance if only our Caucasian doctors are accepted in the armed forces. Such a situation then resolves itself to this conclusion: that because they are Japanese they are literally enjoying protection and immunity and are being given a favored place in the scheme of things, since they are allowed to remain behind to build up lucrative practices which should belong to Caucasian citizens rather than to alien Japanese physicians or American born Japanese not acceptable for military duty.

The operation of the Selective Service laws as now being conducted in the Territory make no racial distinctions. Japanese are inducted alike with all the other races. The board of the Procurement and Assignment Service finds it very hard to reconcile the attitude

of the Surgeon Generals in refusal to accept Japanese commissioned officers when they do accept in the Army Japanese draftees and volunteers. The board of the Procurement and Assignment Service therefore has come to the conclusion that it cannot, in fairness to the citizens of Hawaii who also need good medical care, certify as available only a large number of Caucasians, to the detriment of the white population and to the distinct advantage of the Japanese race. It is to be noted here, in fairness to the American born Oriental physician, that a large number of these boys are very desirous of entering the military service if for no other reason than to show the American public that they are good American citizens.

To date 36 physicians from Hawaii have already entered the armed service, and 37 additional physicians have been certified as available. Of this number 19 are Caucasian, 3 Chinese and 15 Japanese.

All Hawaii has been rated as number 1 for critical wartime classification purposes. From my remarks you can understand just how disastrous has been and continues to be the effect of the war on Hawaii. As an outpost for national defense, as a supply port for all Pacific operations and as a rest and recreational zone for the millions of service men, you can readily understand the tremendous changes that must have taken place in our formerly peaceful islands.

1013 Bishop Street.

Clinical Notes, Suggestions and New Instruments

REACTIONS FOLLOWING MASS ADMINISTRATION OF SULFADIAZINE

COLONEL RUSSELL V. LEE
MEDICAL CORPS, ARMY OF THE UNITED STATES

Because of the large number of persons involved and the importance of learning the frequency of reactions following the administration of sulfadiazine, this report seems justified. As a prophylactic against pneumococcal, streptococcal and meningococcal infections 25,000 men and women were each given a single dose of 2 Gm. of sulfadiazine during a five day period in December 1943. Thus an unusual opportunity was furnished for observing sulfonamide reactions.

The drug was given under the supervision of a medical officer as a single dose of 2 Gm., in most cases immediately after breakfast. Those receiving it were instructed to drink two glasses of water and to refrain from exercise and alcohol for twenty-four hours. The men were instructed to report any untoward effects and, if known to be sensitive, were advised to refrain from taking the drug until such cases could be individually investigated. As is inevitable, however, in such a large number of persons, a few who knew they had had reactions previously did take the drug, and these persons developed the most serious group of reactions.

A total of 128 reactions (0.51 per cent) came to the observation of the medical officers. Of these, 9 (0.036 per cent) were serious enough to require hospitalization. Four more were listed as serious but hospitalization was not done, making a total of 13 (0.052 per cent) in this group. An additional 115 (0.41 per cent) of "mild reactions" were seen in the dispensaries. These can well be described by groups as (a) mild, cutaneous, (b) mild, general, (c) severe, cutaneous, (d) severe, general, and (e) serious, general.

(a) *Mild, Cutaneous* (15 patients).—These were persons who exhibited a mild, generalized erythematous or follicular rash of short duration. It is likely that there were a good many more of these that did not come under observation. An interesting

The author is Chief of Professional Services, AAF Regional Hospital, Santa Ana Army Air Base, Santa Ana, Calif.

feature was that almost all of these showed a greater or less degree of conjunctival injection, which was a definite feature of the more severe cases. The only treatment advised was to take a large amount of water.

(b) *Mild, General* (100 patients).—These persons complained of a variety of symptoms, in the order of frequency malaise, nausea, diarrhea, vomiting and faintness, which were attributed, either by the patient or by the medical officer, to the drug. It is not unlikely that other causes may have been operative in some of these men, and, in view of the fact that they were warned to be on the lookout for untoward symptoms, the psychic factor cannot be disregarded. Rest and a high fluid intake were the only therapeutic measures, and all this group were well within twenty-four hours.

(c) *Severe, Cutaneous* (4 patients).—Two of these patients developed an exfoliative dermatitis which required treatment over a period of days. Both of them had had previous reactions to the drug, 1 of them having developed an exfoliative dermatitis on a previous occasion when he had a local application of a sulfonamide in an ointment. Two others developed edema, somewhat suggestive of angioneurotic edema, which, however, yielded readily to injections of epinephrine.

(d) *Severe, General* (6 patients).—It seems best to list these separately, with a brief summary of each case:

CASE 1.—The man received 2 Gm. of sulfadiazine at 3 p. m. Chilly sensations occurred at 7 o'clock. He was admitted to the hospital at 9 p. m. with a temperature of 99.6 F., weakness, malaise, mental haziness and depression. No abnormal physical manifestations were observed except conjunctivitis. Treatment consisted of forced fluids. The temperature the next afternoon was 99.6 F. The patient was normal and asymptomatic on the third day. The most evident symptom was mental confusion.

CASE 2.—Two grams of sulfadiazine was administered at 2:30 p. m. Chills occurred at 7 p. m. The patient was hospitalized at 8 o'clock with a temperature of 99.6 F., clouded sensorium and conjunctival injection, but no rash. He had taken the drug in September 1943 and his temperature rose to 104 F. afterward. He was afebrile and asymptomatic at twenty-four hours. Treatment consisted of forced fluids.

CASE 3.—A woman was given 2 Gm. of sulfadiazine at 10 a. m. She had pain in the eyes and lacrimation at 1 o'clock with chills and fever to 101 F. At 7:45 a generalized rash appeared, swelling of the eyelids and upper lip and a temperature of 102.4 F. (maximum). The fever lasted thirty-six hours. At 4:30 p. m. there was generalized edema. By next day all swelling except that of the hands had disappeared. Forty-eight hours later the patient was practically normal again. She had taken a sulfonamide compound in July 1943 for otitis and had a rash at that time which lasted for three days and looked like measles but with no conjunctivitis at that time.

CASE 4.—The patient was given 2 Gm. of sulfadiazine at 10 a. m. He was admitted at 3 o'clock with headache, vomiting, loose stools, chills, fever, photophobia, a temperature of 103 F. by evening, which was normal next morning, the skin showing a general blush and the conjunctivas much injected. In June 1943 he had been given sulfadiazine and developed "measles" two days after stopping the drug. It is not certain whether this really was measles or a reaction.

CASE 5.—Two grams of sulfadiazine was given at 9:30 a. m. By afternoon burning and itching of the entire body occurred. At 4 p. m. the eyes were swollen. Physical examination showed considerable edema of the face, lip and orbital regions, with edema extending down in the neck. The concentration of sulfadiazine was 4.1 mg. per hundred cubic centimeters of blood. Epinephrine was given, and the edema promptly subsided.

CASE 6.—Two grams of sulfadiazine was given at 9:30 a. m. By noon intense general redness of the skin and pronounced edema of the feet and legs half way to the knee had developed, with exfoliative dermatitis the next day. The patient had moderate general malaise, with a temperature of 99.6 F., anorexia and slight nausea. The dermatitis still persisted after two weeks. General symptoms subsided in thirty-six hours.

(c) *Serious, General* (3 patients).—CASE 1.—A man aged 31 was given 2 Gm. of sulfadiazine at 4:30 p. m. Headache,

dizziness and pains in the joints and legs had developed by 6:20 and fever at 7 o'clock, with chills and generalized pains, which were very severe; the legs were stiff. He was at his home. He went to bed at 11:30. His temperature was 102 F. He went to sleep. At 1:30 a. m. he vomited; his temperature was 104 F. He called the medical officer next morning and was admitted to the hospital semicomatose, going on to coma, the temperature 104 F., rising to 105.8. Physical examination showed general flushing of the skin, generalized edema, pronounced swelling of the finger tips and conjunctivitis. There was no pulmonary edema. The patient was comatose about six hours and then decidedly irrational. Breathing was difficult, with audible rhonchi. A generalized maculopapular rash developed. Intravenous dextrose was given, epinephrine and atropine, with continuous oxygen inhalations. The patient came out of coma in about twenty-four hours. The temperature, which reached the highest point, 105.8 F. rectally, twenty-four hours after the drug was taken, dropped to 103 the next day, 99.6 the third day, and was normal on the fourth day. The patient was critically ill for thirty-six hours but went on to complete recovery. He had taken sulfadiazine before, in June 1943, when he developed a temperature of 104 F. and a generalized rash, both of which cleared up promptly after the drug was stopped.

CASE 2.—Two grams of sulfadiazine was given at 6 p. m. Next morning chills and fever had developed, with general malaise and headache. The patient collapsed and entered the hospital at 7 p. m. Physical examination showed slight edema of the skin of the face and lips, flushed face and red pharynx. The temperature was 104 F. on entry, rose to 105.6 by evening and was normal the next day. The patient was treated with intravenous dextrose and epinephrine and went on to uneventful recovery in three days. Moderate stupor was present during the febrile period. There was no history of previous sulfonamide administration.

CASE 3.—Two grams of sulfadiazine was given at 9 a. m. At 9:30 the patient became dizzy, and his throat was parched. At 10:30 he could not walk because of vertigo and became unconscious. He was admitted to the hospital at 1 p. m. with pain in the chest, dyspnea and delirium. Owing to misapprehension of his condition he was given two additional doses of sulfadiazine, 2 Gm. and 1.5 Gm. four hours later, and his condition became worse, with coma and severe dyspnea. Sulfadiazine was stopped. He was given intravenous dextrose, and his condition improved rapidly. His temperature fell to normal on the third day, and on the fourth day he was entirely normal. He showed a scarlet flush of the skin, edema of the eyelids and upper lip, and mild conjunctivitis. The concentration of sulfadiazine was 10.7 mg. per hundred cubic centimeters of blood and 5.7 mg. per hundred cubic centimeters of spinal fluid. He had two previous reactions to sulfadiazine in April 1943 and July 1943, on each occasion having fever, vomiting and stupor.

COMMENT ON SERIOUSLY ILL PATIENTS

The remarkable feature of these 3 cases was the high fever and the mental state, which ranged from coma through delirium to mild confusion. Patient 1 of this group was critically ill and might easily have died had not proper therapeutic measures been instituted. It is noteworthy that most of the seriously ill patients gave a history of previous administrations of sulfonamide drugs and previous reactions. As soon as close medical supervision was given to the administration of sulfadiazine, and persons who were known to be sensitive were thereby discovered and prevented from taking the drug, there were practically no more of the serious febrile reactions.

SUMMARY AND CONCLUSIONS

After 2 Gm. of sulfadiazine was administered to 25,000 persons, 0.50 per cent showed reactions, 0.036 per cent showed serious reactions and 3 patients were critically ill.

Treatment with intravenous dextrose and epinephrine was efficacious in the severe reactions.

No cases of urinary suppression or of agranulocytosis were observed.

A careful history of possible previous sensitization should be obtained before sulfonamides are administered.

PATHOGENIC BACTERIA, RICKETTSIAS AND VIRUSES AS SHOWN BY THE ELECTRON MICROSCOPE

THEIR RELATIONSHIPS TO IMMUNITY AND
CHEMOTHERAPY

II. RELATIONSHIPS TO IMMUNITY

STUART MUDD, M.D.

PHILADELPHIA

THE MICROBIOLOGIC SCALE OF PARASITISM

The bacteria, rickettsias, pleuropneumonia-like organisms and viruses are the smallest and simplest known forms of life. These microscopic and ultramicroscopic forms may be arranged in a scale of diminishing size and complexity of organization. This scale in general parallels a scale of diminishing metabolic independence and of increasingly obligatory parasitism. No implication is intended that such an arrangement rests on genetic relationship. No preference is implied either between the hypothesis that the viruses represent primitive forms from which more complex forms of life have evolved⁷⁶ and the alternative hypothesis that the viruses are degenerate forms which have lost in their parasitic habit the means for their own independent existence.⁷⁷ Either hypothesis can be supported, but without decisive evidence. Arrangement of these minute forms in a microbiologic scale, even if somewhat artificial, however, does afford a certain rational continuity in the consideration of their structure and organization and of their relations to immunity and chemotherapy.

Bacteria are of course the largest of these micro-parasites. Bacteria have a definite cellular morphology. In metabolism bacteria range from autotrophic forms to highly parasitic forms. The autotrophic forms are capable of growth on an inorganic substrate and using either sunlight or oxidation of such material as sulfur or ammonia as a source of energy; they must therefore be fully endowed with the enzymes and metabolic systems essential for the synthesis of all the components of their protoplasm.⁷⁸ This protoplasm is as complex, however, as that of other bacteria and of higher forms of life.

The parasitic forms are deficient in one or many of the synthetic mechanisms essential to their growth and therefore dependent on their hosts to supply certain growth factors. The growth factors already known to be required by one or more parasitic bacteria include most of the amino acids, purines, pyrimidines, fatty substances (e. g. oleic acid), vitamins and more

complex substances (e. g. hemin and coenzyme for *Hemophilus influenzae*⁷⁹ and phthiocol for *Johne's bacillus*).⁷⁸

In pathogenicity bacteria range from free living forms which cause disease only through accidental ingestion of their toxic metabolic products, as in the case of *Clostridium botulinum*, through "opportunistic invaders" such as streptococci and staphylococci, to obligate parasites such as *Treponema pallidum* and *Mycobacterium leprae*, which have rarely if ever been cultivated in their virulent state outside the body. Defense against bacteria is feasible through specific active and passive antitoxic and antibacterial immune mechanisms and by means of currently available chemotherapeutic and antibiotic agents.

Rickettsias are smaller than bacteria but have essentially similar cellular morphology.⁸⁰ The pathogenic rickettsias have either lost or never achieved their metabolic independence, can be cultivated only in the presence of cells and are intracellular in their parasitic habit.⁴⁴ Specific preventive measures are in practice against rickettsial diseases but specific measures for treatment are not as yet known.^{80a} Successful chemotherapy of louse borne typhus fever by para-aminobenzoic acid is also currently described.^{80b}

The known viruses range in size from those of the psittacosis-lymphogranuloma group and the pox diseases, through influenza virus and the bacteriophages, down to the plant viruses, which are "macromolecules." A typical large virus, vaccinia, has been shown to have an essentially cellular morphology, with cell wall and differentiated inner protoplasm.⁵¹ The bacteriophage particles, which are smaller than vaccinia, still have a complex morphology; they must be at or near the limit of cellular organization. The plant viruses, as far as now known, are giant molecules; the best studied of the macromolecular viruses appear to be composed solely of nucleoprotein.

The viruses are metabolically dependent on the cells within which they are obligate intracellular parasites. Specific active and passive prophylactic measures are in general very effective against virus diseases, but in general both specific immune and current chemotherapeutic measures are of very limited therapeutic value in viral diseases. Specifications for effective chemotherapeutic agents against viruses can be drawn up, however, and there are reasons for hoping that such agents may eventually be realized in practice, as will be discussed later.

THE MORPHOLOGY OF THE MICROPARASITES IN RELATION TO IMMUNITY

Bacteria and rickettsias as examined by ordinary bacteriologic methods appear to be simple and structureless. Special methods, of course, may serve to demonstrate flagella, capsules and even cell walls.¹⁴ But the long habit of observing such minute and apparently simple objects is often reflected in methods of dealing with bacteria in practice as though they were much

Dr. Mudd was chairman of the Committee on Applications of the Electron Microscope, National Research Council, 1940-1944.

The privilege of republishing certain of the electron micrographs was extended by the authors and the journals cited in the corresponding references in the bibliography and by the Williams and Wilkins Company, Baltimore.

The first instalment of this paper, on Morphology, by Stuart Mudd, M.D., and Thomas F. Anderson, Ph.D., appeared in *THE JOURNAL* October 28, p. 561. Illustrations referred to in the present paper which did not appear in the preceding instalment will appear in the reprints.

simpler than they actually are. The vivid demonstration by the electron microscope of structural differentiation within the cells of bacteria, rickettsias and even the larger viruses should lead to the further development of discriminating methods of using micro-organisms as diagnostic agents and as the means for producing active and passive immunity.

Immunity Against Bacteria.—Diagnostic Reactions: Theobald Smith and Reagh⁸¹ in 1903 demonstrated the structural and immunologic distinctness of the antigens, respectively, of the flagella and of the cell wall of *Salmonella cholerae-suis*. Analyses of the reactivities of the several flagellar and somatic antigens of more than a hundred intestinal pathogens of the typhoid-paratyphoid-food poisoning group are now available and are systematized in the Kauffmann-White or International schema,⁸² which is the current standard for classification and etiologic diagnosis within that group. Electron micrographs of the cells and flagella of typhoid bacilli and their modification by specific immune serums are shown in figures 47 and 48.

Avery and Heidelberger⁸³ demonstrated the structural and immunologic distinctness of the antigens respectively of the capsules and of the cells of pneumococci. The specific capsular polysaccharides proved to be the practically important antigens of the pneumococci. The diagnostic capsular swelling phenomenon,⁸⁴ the Francis skin test and the choice of type specific therapeutic serums are all based on the specific reactivities of the respective capsular polysaccharides. Electron pictures of the capsular swelling reaction are shown in figures 23 and 24.

A more recent example of a localized bacterial component used as a diagnostic reagent, in the preparation of which insight gained with the electron microscope was used, is the agglutinin of virulent *Hemophilus pertussis*, which is currently proving useful as a reagent for estimating susceptibility to whooping cough.⁸⁵ The pertussis agglutinin was at first prepared by methods predicated on the assumption that the cells of *H. pertussis* should first be disintegrated to liberate the agglutinin.⁸⁵ Later, reasoning that the agglutinin was a component of the surface of the cells of virulent *H. pertussis* led to the successful attempt to extract surface material directly from the intact bacterial cells.⁸⁶ This surface extraction provided the diagnostic agglutinin in better yield by a simpler procedure than the earlier method.

The pneumococcus capsular polysaccharide used in the Francis test and the pertussis agglutinin, phase 1, used for the skin test for pertussis, are of themselves nontoxic and give allergic skin reactions only as the result of the existence of antibodies

in the skin, present in consequence of earlier infection, vaccination or serum therapy. The pneumococcus or pertussis bacterial cells, since they are of complex composition and appreciably toxic, are not equally suitable for such specific diagnostic tests. The specific somatic surface antigens of the typhoid-paratyphoid-dysentery group are, on the contrary, inherently highly toxic⁸⁷ and are thus not suitable for such specific skin tests.

The Preparation of Vaccines and Immune Serums: The virulence of a pathogenic agent may be defined as its ability to cause disease; virulence is thus defined as synonymous with pathogenicity. Virulence or pathogenicity may be considered as comprising in some instances two factors, invasiveness and toxigenicity. Invasiveness obviously means the micro-organism's capacity to penetrate and subsist within the tissues of the host. Toxigenicity for the purposes of this discussion means the capacity to elaborate an exotoxin, as exemplified by *Corynebacterium diphtheriae*, *Clostridium tetani*, *Cl. botulinum*, *Cl. welchii*, *Bacterium shigae*, *Streptococcus pyogenes* and *Staphylococcus aureus*. Invasiveness and toxigenicity may not always be separable in actual infection; the practical utility of considering these factors separately, however, arises from the fact that the immune mechanisms and therapeutic agents required to combat invasiveness and toxigenicity are distinct. This distinctness arises from the fact that the bacterial components against which the anti-invasive (antibacterial) and the antitoxic defensive mechanism are directed are structurally and chemically distinct.

Anti-Invasive (Antibacterial) Immunity: The ability of a pathogenic agent to establish itself on and to invade its host doubtless depends on the whole complex of relationships between parasite and host: the metabolic requirements of the pathogen in relation to the nutrition and oxygen tension provided in host tissues, the ability of the pathogen to withstand host defensive mechanisms, and so on. Specific active and passive immunity against invasiveness, however, is dependent primarily on the antigens at the surface of the pathogen. The first and essential step in the action of antibodies, whether actively or passively acquired, against the invading pathogenic agent is specific chemical combination with an antigen or antigens at the surface of the pathogenic agent. Agglutination, antibody-complement bactericidal action or phagocytosis by polymorphonuclear or mononuclear⁸⁸ phagocytes may follow as a consequence of this specific union of antibody with surface antigen, depending on the nature of the pathogen and the environing conditions. The antigens of the cell wall of the pathogenic agent in its virulent form are therefore the primary requisite of any diagnostic reagent or vaccine which is to detect or stimulate anti-invasive immunity. Since electron microscopy shows that the cell walls of bacteria and rickettsias form a relatively small fraction of the mass of the cells and since the inner protoplasm may be toxic, these facts have practical implications. It is perhaps not too rash to predict that purified surface antigens will increasingly come into use as diagnostic reagents and even as vaccines for active immunization.

The pneumococcus polysaccharide used in the Francis skin test in pneumonia and the agglutinin of *Hemophilus pertussis* used in the diagnosis of susceptibility to pertussis have already been cited as examples of the use of specific surface components for susceptibility tests.

Type specific serologic reactivity, on which specific antibacterial immunity depends, may be determined by configuration either of a carbohydrate or of a protein component. The capsular polysaccharides of the various pneumococcus types are the classic examples of carbohydrate antigens which determine type. The surface somatic proteins ("M substance") of the various types of *Streptococcus pyogenes* are an example of type determination by protein antigens. In the case of the typhoid-paratyphoid-dysentery group, type specificity is determined by a phosphorus-containing polysaccharide-protein complex in which the carbohydrate component is type specific and the protein component is not type specific.⁸² The characteristic antigenic reactivity (and toxicity) of the somatic antigens of this group appear, however, to be a property of the intact phosphorus-containing polysaccharide-protein complex and not of either the isolated carbohydrate or protein component alone.⁸⁷ In all cases known to me, however, the reactive configurations which determine type specificity and antibacterial immunity are peripheral,⁸⁹ i. e. are in the capsule, as in pneumococci, in the bacterial cell wall, as in *Streptococcus pyogenes* and the *Shigellas*, or in the bacterial cell wall and flagella, as in *Eberthella typhosa* and the *Salmonellas*.

Emphasis on the selection of pathogens in fully virulent form as a source of antigens for detecting or producing anti-invasive immunity perhaps requires further elaboration. Evidence is slowly accumulating from many sources to indicate that the specific, pathogenic types of bacteria represent highly differentiated phases which are characteristically found under conditions of active and successful parasitism. These specific differentiated phases may, under favorable conditions, persist in culture. Usually, however, type specificity and pathogenicity tend sooner or later to diminish or be lost under artificial cultivation. Loss of type specificity usually proceeds *pari passu* with loss of an antigenic component at the surface of the parasite, for instance of the capsular polysaccharides of virulent pneumococci, the Vi somatic polysaccharide of virulent *E. typhosa*, the M protein present in the cell wall of virulent *Str. pyogenes*²⁵ or the agglutinin of *Hemophilus pertussis* in phase I;⁹⁰ loss of type specific surface antigen is usually correlated also with loss of invasiveness. Such nonpathogenic phases, which have lost the surface antigens associated with virulence, are obviously unsuited as immunizing agents to protect against invasion.

The ability to elaborate exotoxin (toxigenicity), on the other hand, may persist without relation to loss of type specific surface antigens and of the component of virulence on which depends the ability of the parasite to establish itself on and to invade its host.

Antitoxic Immunity: The diseases which are primarily due to the production of exotoxin are those in which specific biologic prophylaxis and treatment have had their most conspicuous successes. Diphtheria, tetanus and to a less extent scarlet fever are cases in point. The exotoxin elaborated by the growing pathogenic agent passes out of the bacterial cell into the culture medium or host tissue and exerts its toxic action at a distance from its source. In diphtheria and tetanus early neutralization of the exotoxin by specific antitoxin usually suffices to permit recovery, the defensive mechanisms of the host in due course serving to eliminate the parasites themselves. In streptococcal and staphylococcal infection neutralization of the exotoxins does not of itself necessarily suffice to prevent tissue invasion by the streptococci or staphylococci themselves.

Exotoxin is ordinarily harvested from aged cultures in which many or most of the bacterial cells are cytolized. Morton and Gonzalez,⁹¹ however, obtained diphtheria toxin from young cultures of *C. diphtheriae* by sonic disintegration of the bacterial cells. The exact site of formation of toxin by the bacterial cells is not known. Only one type of toxin is known to be produced by *C. diphtheriae* or by *Cl. tetani*, although the cells of the diphtheria or tetanus bacilli occur in several agglutinative types.

Since exotoxins and toxoids as ordinarily dealt with are free from the cells which produced them, and since their relation to the architecture of these cells is unknown, their further discussion would be outside the scope of the present article.

Immunity Against Viruses.—The immune mechanisms which are operative against bacteria and other foreign particles containing antigens are also operative against viruses.⁹² Specific combination of viral antigen and corresponding antibody can be demonstrated *in vitro* by precipitation, agglutination or complement fixation, and *in vivo* by specific neutralization of virus infectivity. The combination of virus and specific antibody has been demonstrated in electron pictures by Anderson and Stanley⁹³ (figs. 49 and 50). The blood clearing mechanism, consisting of the fixed reticulo-endothelial macrophages, the wandering macrophages, the circulating monocytes and polymorphonuclear leukocytes, acting in coordination with antibodies, is operative against viruses. Virus neutralizing antibodies are extremely effective in protecting animals against experimental virus infections. Clinical protection following exposure to various virus diseases may be afforded under appropriate conditions by convalescent human serums. Active immunization or recovery affords some degree of protection against most or all virus diseases. In brief, the classic phenomena of active and passive immunity and allergy are exhibited with respect to viral and rickettsial infections, but with modifications consequent on the obligate intracellular sites of the infecting viruses and rickettsias.

Active and passive humoral immunity (i. e. immunity dependent on antibodies) is of more conspicuous value in diseases due to intracellular parasites if established prior to the onset of clinical symptoms than for the treatment of established infection. The commonly

89. By "peripheral" is meant present in the periphery of the cell, without implication, however, that the component may not be present also in the inner protoplasm of the bacterial cell. It may be emphasized also that antigens of bacterial flagella may be of cardinal importance for that antigens of bacterial flagella may have only a very minor role in antibacterial diagnostic purposes but have only a very minor role in antibacterial immunity.

accepted explanation is that once intracellular parasites (chiefly the rickettsias and viruses) have parasitized their host cells they are no longer accessible to the action of immune serum. This pessimism regarding specific therapy would doubtless be justified if all the susceptible cells which are ultimately affected were parasitized at the same time. However, in a recent article on this subject Stokes⁹⁴ offers evidence that measles may be modified to some extent if sufficient human antibodies are administered in its earliest febrile stage. Topping⁹⁵ presents similar data for experimental animal and for clinical human cases of Rocky Mountain spotted fever. Stokes emphasizes the importance of earlier diagnosis of such diseases so that the therapeutic as well as prophylactic possibilities of such newly available preparations as Cohn's human γ -globulin concentrate may be realized.

Another phenomenon of acquired resistance has most recently been proved to exist in a number of viral infections. This phenomenon of acquired cellular resistance is quite outside the classic phenomena of immunity as described in infections caused by extracellular parasites. Whether or not this phenomenon may ultimately prove to be coextensive with intracellular parasitism and what its practical implications may be it is as yet too early to predict. Its possible importance as well as its relative unfamiliarity suggest discussion of the interference phenomenon or the phenomenon of acquired cellular resistance in considerable detail.

The Interference Phenomenon in Viral Diseases; Acquired Cellular Resistance.—A growing body of evidence shows the existence in viral diseases of a phenomenon involving a specific relationship between viruses and host cells, and specific interference between related viruses in the parasitizing of their host cells. The challenging question of the extent to which this phenomenon may be related to active resistance to superinfection during infectious diseases due to intracellular parasites, in carrier states and following recovery from such diseases is worthy of much consideration.

The most clearcut instances of the interference phenomenon consist in the protection, within strict limits of time, dosage and other factors, of host cells ordinarily susceptible to a virulent virus by the presence of a related⁹⁶ virus. The protection may be afforded by a virus of such low virulence with respect to the host cells in question that minimal or even no symptoms are observable; the protective action may be initiated by the related virus prior to or simultaneously with infection with the virulent virus. This phenomenon of interference between related viruses has been described with respect to animal, plant and bacterial (bacteriophage) viruses.

Interference Between Animal Viruses: Magrassi⁹⁷ first observed in Doerr's laboratory in 1935 a phenomenon of immunity against superinfection which was not satisfactorily explicable in terms of humoral immunity. Magrassi worked with strains of herpes virus,

certain of which were capable and certain incapable of causing encephalitis in rabbits. Following corneal infection with a nonencephalitogenic strain the rabbits did not develop any clinical signs of encephalitis; nevertheless the virus could be demonstrated to be present in the brain on the sixth day following intra-corneal inoculation; from the fourth day after corneal inoculation the animal was immune to direct cerebral inoculation even of large doses of encephalitogenic virus. Magrassi similarly demonstrated that, from five to ten days after intracutaneous inoculation of herpes virus, rabbits were immune to cerebral reinoculation with the virus; the reinoculated virus indeed disappeared rapidly from the brain, and this disappearance was not explicable as a neutralization by antibodies. Magrassi's essential observations were confirmed by Doerr and Seidenberg,⁹⁸ and the significance of these and similar experiments were discussed by Doerr and Kon.⁹⁹

Hoskins¹⁰⁰ in 1935 observed that *Macacus rhesus* monkeys injected subcutaneously or intraperitoneally with mixed pantropic and neurotropic strains of yellow fever virus were protected by the neurotropic strain from fatal infection by the pantropic strain. The same protective effect against pantropic virus was afforded if the neurotropic strain was injected separately up to twenty hours after the pantropic strain; if injection of the pantropic virus preceded injection of the neurotropic strain by forty-eight hours, however, there was no protection and the animals died of infection with the pantropic strain.

These observations were confirmed and extended by Findlay and MacCallum.¹⁰¹ Protection against pantropic yellow fever virus was afforded by concurrent injection of neurotropic yellow fever virus in several host species. Rift Valley fever virus also afforded some protection to monkeys against pantropic yellow fever virus. Neurotropic yellow fever virus in turn protected mice against Rift Valley fever virus. The authors offered as a possible explanation of these instances of interference of one virus with the pathogenic action of another virus the hypothesis "that when certain cells are already occupied by actively multiplying virus particles they cannot be invaded by certain other virus particles."

Jungeblut and Sanders¹⁰² similarly demonstrated interference between a mouse adapted and a monkey strain of poliomyelitis virus. The presence of murine virus in the monkey brain was shown to interfere critically with the propagation of virulent monkey strains in the same animal. This effect could be produced therapeutically up to four days after intracerebral inoculation of the virulent virus. Thus "among a total of 88 monkeys which had received murine virus between the first and fifth day of the disease, 51 monkeys, or more than half (57 per cent), failed to show paralytic symptoms, while in a group of 50 untreated controls

96 The term "related" is used without for the present attempting precise definition. In many but definitely not in all cases in which data are available, interfering strains are serologically cross reactive. Probably all that should be implied at this time is that interfering viruses parasitize the same host cells in some competitive manner.

only 2 monkeys (4 per cent) escaped the disease." In seeking an explanation the authors point out that both murine and monkey strains of the virus "possess the same affinity for the anterior horn cell which constitutes the selective seat of the poliomyelitic lesion . . . A 'blockade' of susceptible cells by nonparalyzing murine virus might render these cells temporarily impregnable to an attack of paralyzing monkey virus because the orderly function of certain enzyme systems, necessary for successful propagation of monkey virus, has conceivably been disturbed by previous contact with murine virus."

Protection of hamsters against a hamster adapted strain of poliomyelitis virus by previous inoculation with various other strains of poliomyelitis virus has recently been described by Dalldorf and Whitney:¹⁰³ "The protection is well developed within six days and persists for from six to eight weeks." As in other instances, heat inactivated virus does not afford this protection; . . . "the time relationships are important in showing that the phenomenon is an interference rather than cross immunity."

Reciprocal interference between strains of influenza virus grown in tissue cultures has been demonstrated by Andrewes:¹⁰⁴

When a strain of influenza A is given good opportunity to multiply in a tissue culture of the Maitland type, that culture is thereby rendered incapable of supporting the growth of another strain of influenza added subsequently. This cannot be because of any formation of antibody, nor is there any change in pH as compared with uninoculated cultures.

The cells of the infected culture would still support growth of the unrelated virus of lymphogranuloma venereum. "When two strains of influenza A virus were added to a tissue culture simultaneously but in widely differing amounts, the one present in larger quantity suppressed the growth of the other."

The Henles,¹⁰⁵ studying the propagation of influenza A virus in the chorioallantoic membrane of embryonated eggs, have demonstrated interference by homologous virus partially inactivated by aging or by ultraviolet irradiation:

Similar interference experiments conducted in mice by the intranasal injection of partially inactivated virus preparations, followed five hours later by the active agent, have given results indicating that the same phenomenon may be demonstrated in this species. Protection against as much as 250 50 per cent mortality doses was noted

Interrelationships between classic immunity and the phenomenon of acquired cellular resistance are well brought out by the studies of Morgan and Olitsky,¹⁰⁶ Morgan, Schlesinger and Olitsky¹⁰⁷ and Schlesinger, Olitsky and Morgan.¹⁰⁸ A degree of active immunity

can be induced in animals by vaccination with formaldehyde inactivated eastern equine encephalomyelitis virus or western equine encephalomyelitis virus. In such vaccinated animals the degree of resistance to intracerebral inoculation of homologous virus is correlated with the titer of neutralizing antibody in the serum and with the neutralizing capacity of the cerebrospinal fluid.¹⁰⁷ Animals vaccinated with formaldehyde inactivated eastern equine encephalomyelitis virus are not immunized against western equine encephalomyelitis virus, nor are those vaccinated with western equine encephalomyelitis virus immune to eastern equine encephalomyelitis. This is the familiar picture of specific active immunity.

If now such vaccinated guinea pigs were injected intracerebrally with 1 to 1,000 minimum lethal dose of homologous virus a steep rise in temperature occurred, first observed two hours after inoculation and persisting for about twenty-four hours; while in control animals fever lasted until prostration or death, in immune animals the temperature dropped after twenty-four to thirty hours and remained normal thereafter.¹⁰⁸ Guinea pigs two weeks after this abortive infection with western equine encephalomyelitis virus resisted intracerebral reinoculation with 10 or 1,000 minimum lethal doses of eastern equine encephalomyelitis virus. Similar observations were made in rabbits. Animals thus rendered resistant to reinoculation intracerebrally with either homologous or heterologous virus were not resistant to peripheral reinoculation with heterologous virus, which circulated in the blood stream as in normal animals. Animals vaccinated and then recovered from an abortive infection with western equine encephalomyelitis exhibited also an increased resistance to intracerebral inoculation with Theiler's virus. This, then, is the picture of the interference phenomenon—an induced, transient resistance to superinfection of cells which would normally be susceptible, this acquired cellular resistance not being necessarily limited to serologically cross reactive types of intracellular parasite

The interference phenomenon has recently been investigated in detail by Ziegler and Horsfall,¹⁰⁹ Ziegler, Lavin and Horsfall¹¹⁰ and the Henles,¹¹¹ using embryonated hen's eggs inoculated into the allantoic sac with influenza virus. Reciprocal interference has been clearly demonstrated between strains of influenza A, influenza B and swine influenza virus. These strains are related in their tropism for tissue but are not serologically cross reactive. Suppression of reproduction of active virus was obtained by the presence of active heterologous virus or of homologous or heterologous virus rendered partially or completely noninfective by carefully quantitated ultraviolet radiation or by prolonged storage at low temperature. Reproduction of active virus could be suppressed by introduction of noninfective virus as long as twelve hours after inoculation of the active virus.

Interference Between Plant Viruses.—The literature on acquired immunity of plants to viral diseases has been reviewed by Price.¹¹² Many plants recover symptomatically from virus disease but remain carriers of viable virus. Such plants are immune to reinoculation of the same or related viruses but not to unrelated viruses:

Plants recover after an acute attack by production of shoots or leaves which appear healthy or show only mild symptoms of disease, which still harbor virus and which are refractory to infection with the virus in question but not to infection with unrelated viruses.

With respect to cross immunity, it has been shown with numerous groups of viruses that plant tissues invaded by one strain of a virus are protected from infection with another strain of the virus but are susceptible to infection with unrelated viruses. The immunity appears to be closely associated with presence of virus in the immune tissues, since there is no evidence that virus free tissues of infected plants are immune. The cross immunity reaction has proved useful for differentiation and classification of plant viruses.

Kunkel¹¹³ records an instance in which this interference between plant viruses was of curative value during the first days of infection. A mild strain of tobacco mosaic virus was used to immunize tomato plants against a lethal strain of tobacco mosaic virus which quickly kills unprotected tomato plants. The tomato plants were saved from death or serious injury when they were inoculated with the mild virus within three days after infection.

It is to be emphasized that nothing equivalent to antibodies and therefore no natural humoral mechanism of immunity has been demonstrated in plants. It is true that specific neutralization of the infectivity of plant viruses by immune serums prepared in animals can be demonstrated experimentally; this, however, is definitely an artificial procedure. Price presents interesting considerations suggesting that the type of specific acquired immunity under discussion may be common to animals and plants alike.

Interference Between Bacterial Viruses (Bacteriophages).—The lysis of bacteria by bacteriophage may be considered as a virus infection in which the susceptible bacterial cell is the host and the bacterial virus or bacteriophage particle is the parasite. The accessibility of the bacterial cell to observation, the simplicity of the host (simplicity at least as compared to animal and plant hosts) and the short time within which the parasitic cycle is complete make bacteriophage lysis peculiarly suitable for definitive analysis.

Interference between types of bacteriophage active against a single strain of *E. coli* has been demonstrated and analyzed by Delbrück and Luria,¹¹⁴ Luria and Delbrück¹¹⁵ and Luria, Delbrück and Anderson.¹¹⁶ Two different types of bacteriophage, α and γ , each independently produce characteristic lysis of the susceptible strain of colon bacilli. In mixed infection under suitable conditions, however, lysis is exclusively of the γ type, and lysis by α phage is completely suppressed.

Analysis of lysis by these bacteriophage strains reveals that the first step is adsorption of bacteriophage particle or particles on the surface of the bacterial cell. Unless phage is present in great excess there is no interference between the two phage strains in regard to this primary adsorption; each strain is adsorbed at a rate dependent on its own affinity for the host cell and the experimental conditions.

"The second phase of the life cycle is the multiplication of the virus in the cell. After the bacterial cell has adsorbed a virus particle, it retains normal appearance for a while; then, suddenly, the newly formed virus particles are liberated. In most cases the cell is lysed at the same moment. . . . After this the newly liberated virus particles will become adsorbed to other bacteria still present in the culture." In infection by a mixture of the two phage strains the chain of events between adsorption of virus on cell, through multiplication of the virus, to liberation of new phage particles is dominated by the γ phage. In lysis by the γ phage the latent period between adsorption and liberation of the new phage particles is twenty-one to twenty-five minutes and on the average about 135 new phage particles are released from each cell lysed. These characteristic constants are not altered by the presence in the mixed infection of α phage particles, and the new phage particles produced are exclusively of the γ type. The α phage alone produces lysis in thirteen to seventeen minutes. Yet the suppression of the growth of α phage may be brought about even when γ phage is added several minutes after infection by a phage.

Luria and Delbrück¹¹⁵ found that the ability of γ phage to suppress the growth of α phage could be demonstrated even after the γ bacteriophage was partially inactivated by ultraviolet radiation, although heat inactivated phage had lost this ability. Analysis of the quantitative data led to the conclusion that the adsorption of one ultraviolet inactivated γ particle on the bacterial cell was sufficient to inhibit the growth of virus α :

The ultraviolet inactivated virus γ also shows the capacity of inhibiting the growth of the sensitive bacteria. These are not lysed but deprived of the ability to divide. The number of bacterial cells thus affected corresponds to that of the cells in which the growth of the virus α is inhibited; the two actions evidently are manifestations of the same phenomenon. The suppression of bacterial growth must be due to inhibition by virus γ of some fundamental step in the synthetic processes of the bacterial life cycle.

A bacterium-phage relationship suggestive of the resistant carrier state which is so familiar in animal and plant pathologic conditions has been described by Burnet and Lush:¹¹⁶

A bacteriophage (C) acting on the nonpathogenic white coecus SF is characterized by the unusual frequency with which it provokes the appearance of resistant forms. Each plaque shows a central growth of resistant culture, and suitable experiments indicate that under the usual conditions of growth 10 or 20 per cent of effective contacts between phage and susceptible bacterium result in the appearance of resistant lysogenic variants, the remainder initiating lysis in classic fashion. The resistant culture shows no gross evidence of lytic action on agar but in broth culture liberates considerable amounts of phage.

Concerning the change of the host bacterial cell from normal susceptible to resistant carrier the authors say:

The production of the resistant lysogenic strain SF/C provides a clearcut example of the positive induction of change in bacterial character by the action of a bacteriophage. In this instance the alternative of selection by phage from preexistent variants in the population submitted to lysis is definitely excluded. The rapidity with which the change is induced is noteworthy. Within an hour of contact with phage C the surface of the bacterium has changed so that it no longer adsorbs either phage C or C' and becomes insusceptible to their action. This changed character is then transmitted indefinitely to its descendants. It is not possible to say whether this surface change results from an altered genetic constitution of the bacterium or is directly induced by the associated phage at each generation.

White¹¹⁷ discovered a similar case in cholera bacteriophagy. A phage strain of small lytic power "renders the originally sensitive vibrio forthwith and in perpetuity resistant to the most active" phage strain. The resistant bacteria are lysogenic, i. e. are carriers of phage. Concerning mechanism, White writes "The obvious and highly probable explanation is that the less lytic phage, lacking nothing in combining vigor, establishes itself on the 'phage receptors' of the bacterium, forbidding entry to its more destructive confrère. . . ."

These data on the interference phenomenon in animals, plants and bacteria have been presented in what may seem disproportionate detail because of my belief that they may lead to the threshold of a more fundamental understanding of the relationship of the parasite to the parasitized host cell in many diseases caused by intracellular parasitic agents. They may be considered relevant to a discussion of the morphology of micro-parasites because a critical relationship between components of the parasites and components of the parasitized host cells is involved. In some instances at least the first step of this critical relationship, the adsorption of virus to host cell, may be shown to depend on a specific correspondence in chemical configuration between the virus and components of the host cell surface analogous to that between antibody and cell surface antigen.

The first step in the action of bacteriophage particle on susceptible bacterial cell is specific adsorption of the phage particle to the surface of the bacterial cell. This adsorption must depend on a lock to key correspondence between the pattern of certain molecular configurations on the surface of the bacterial cell and the pattern of configurations on the surface of the phage particle.¹¹⁸ The adsorption of phage to a specific receptor site on the bacterial cell is analogous to the combination of antibody with antigen at the surface of the bacterial cell. Each depends on a specific surface configurational correspondence.

The specificity of the phage receptor and the antigen sites may be closely similar. Thus Schiff and Bornstein¹¹⁹ describe a phage specific for the somatic antigen

IX of the Kauffmann-White table of *Salmonella* antigens. This antigenic configuration occurs in *Eberthella typhosa* and in group D of the *Salmonellas*; bacterial species whose surface contains configuration IX are, with few exceptions susceptible to this particular phage and species lacking IX are not, again with certain exceptions. Another phage lyses bacterial species containing the flagellar antigen *d* which occurs in *E. typhosa* and in certain *Salmonella* species. A similar phage for R somatic antigen is described by the same authors.¹²⁰ On the other hand the Vi phages described by Craigie and Brandon¹²⁰ and Craigie and Yen¹²¹ have permitted the subdivision of the single serologic V type of *E. typhosa* into eighteen types and subtypes¹²¹ as determined by phage susceptibility. Finally within the species *Streptococcus pyogenes*¹²² the specificity of serologic types is narrower than that of the grouping determined by phage susceptibility. Strains of dysentery bacteriophage are available also which lyse strains of several types within the species *Shigella paradysenteriae*. The sites on the bacterial cell with which phages combine may thus be more or less specific or equally specific with the sites at which given antibodies combine. In each case the combination must be critically dependent on molecular configurations in the bacterial cell surface.

Direct evidence that the combination between bacteriophage and susceptible cell is also dependent on the state of the surface of the bacteriophage particle is afforded by the recent study of Kalmanson and Bronfenbrenner.¹²³ These investigators have shown that adsorption of phage particle to bacterial cell can be prevented by previous combination of phage with antiphage serum and that the phage activity can be quantitatively restored by digesting away the antibody coating with the proteolytic enzyme papain. The phage particle coated with antiphage serum cannot combine with the bacterial cell receptors; removal of the antibody from the phage particle surface enables it to combine with and cause lysis of its bacterial host cell.

The chain of events following adsorption of phage particle to susceptible cell surface leads to multiplication of the phage and usually to lysis of the bacterial host cell. d'Herelle¹²⁴ presents evidence suggesting that the phage may elaborate lysins which are distinct from the components which determine adsorption to the susceptible cell. However, the mechanism of phage multiplication¹²⁵ and of bacterial lysis have not yet been clearly analyzed and will not be considered further in this report.

In the work cited a beginning has been made in discovering the all important events that are involved in the parasitization of a host cell by an intracellular parasite. In the case of bacteriophagy at least it seems clear that the initial event is a specific adsorption of the phage particle to bacterial host cell, this combination,

117. White, P. B.: Lysogenic Strains of *V. Cholerae* and the Influence of Lysozyme on Cholera Phage Activity, *J. Path. & Bact.* **44**: 276-278 (Jan.) 1937.

118. This sentence is obviously an interpretation by the author, to whom, however, the conclusion seems almost a rational necessity. Experimentally it rests on the analogy between the specificities of the phage-bacterial cell and the antibody-bacterial cell relationships. That the antibody-antigen combination depends on specific surface configurational correspondence is documented by a large and detailed body of knowledge.

like that between antigen and antibody, being determined by specific configurational relationships. This adsorption of phage particle is followed by profound alterations in the metabolic events which occur within the parasitized cell. Some at least of the consequences have been detected: 1. The host cell may become altered in such a way as to make it refractory to superinfection with similar or competing virus particles (acquired cellular resistance—the interference phenomenon). 2. Multiplication of the bacterial host cell may be arrested. 3. Multiplication of the virus within the host cell may occur without lysis (lysogenic strains). 4. Multiplication of the virus within the host cell followed by lysis may occur.

To what extent may the relationship of bacteriophage particles to their bacterial host cells be regarded as affording a clue to the relationship of virus particles to susceptible cells of higher animals and plants? Obviously this question can now be answered in only the most tentative way. The analogies between the phenomena of acquired cellular resistance (interference phenomenon) as exhibited in viral infections of animals and plants and of bacteria seem to me very suggestive, indeed. Particularly suggestive too is the recent study by Hirst¹²⁶ of the adsorption of influenza virus on cells of the respiratory tract.¹²⁷ The analogies between the protective action of serum in prophylactic passive immunization (e. g. against measles) and the reversible inactivation of phage by immune serum¹²⁸ is suggestive.

Although the phenomenon of acquired cellular resistance to superinfection would appear to be a consequence of the fundamental mechanisms of reproduction within their host cells of many animal, plant and bacterial viruses, interference does not occur in all instances of viral infection. Thus numerous cases are on record of the infection of individual cells by more than one virus,¹²⁹ evidenced by the demonstration, for instance, of specific intranuclear and cytoplasmic inclusion bodies within the same cell. The changes consequent on the parasitization of a cell, in some but not all instances, therefore render that cell refractory to a second intracellular parasite. Although this acquired cellular resistance is a phenomenon separate from humoral immunity, the two phenomena may supplement each other in the total defense against an intracellular parasitic disease.

Is the phenomenon of acquired cellular resistance limited to viral infections? Diseases due to rickettsias have not as yet been investigated with reference to the existence or nonexistence of the interference phenom-

non, as far as I am aware; observations which may be interpreted as suggestive of the possible occurrence of such a phenomenon in rickettsial diseases are recorded in Pinkerton's review.⁴⁴

Phases in which bacterial pathogens survive and even multiply within host cells are not unknown in diseases of bacterial causation, e. g. leprosy and the early stages of tuberculosis. In tuberculosis the physiologic behavior and even the morphology of mononuclear phagocytic cells is altered by ingestion of tubercle bacilli and their products, as well shown in the thorough investigations of Lurie.¹³⁰ Such cells may acquire an increased metabolic activity, as evidenced by increased rate of division and increased rate of phagocytosis, and an increased capacity to destroy tubercle bacilli. Comparison of this altered physiologic behavior with the phenomenon of acquired cellular resistance to intracellular parasitization would be purely speculative at this time, however.

SUMMARY

Electron micrographs of the simplest parasitic agents of disease have afforded new insight into their structure. Bacteria and rickettsias are shown to have a simple cellular organization. The continuity of bacterial groupings, the shape and structural integrity of the individual bacterial cell are dependent on a well defined bacterial cell wall. This cell wall is in the solid state and may maintain its essential form even after injury to the bacterial cell. Within the cell wall is the bacterial protoplasm with its limiting protoplasmic membrane; only the protoplasm and protoplasmic membrane are seen in ordinary microscopic preparations. The protoplasm is either a sol or a gel which may be readily solvated; it may contain more or less well defined areas of greater density. Certain animal viruses and bacterial viruses have also been demonstrated to have simple cellular organization. Plant viruses thus far studied are nucleoproteins without cellular organization.

Increase in parasitic habit among bacteria is in general correlated with loss of metabolic independence, with dependence on growth accessory substances furnished by the host. The capacity to reproduce outside the host's cells is in general retained by pathogenic bacteria, however. Rickettsias and viruses can reproduce only within their host cells, apparently through diversion of metabolic mechanisms of the host cells.

Classic mechanisms of active and passive immunity are operative with respect to bacteria, rickettsias and animal viruses. Antigens present in the periphery of the parasite (bacterial capsule or cell wall) and the antibodies corresponding to these peripheral antigens are determinative with respect to humoral anti-invasive immunity. Exotoxins are metabolites which are specifically neutralizable by antitoxins. In infections due to viruses a phenomenon of acquired resistance of parasitized host cells to superinfection (the interference phenomenon) may occur. This phenomenon is separate from but may supplement the mechanisms of humoral immunity. Whether or not the interference phenomenon occurs in rickettsial diseases remains to be investigated.¹³⁰

126. Hirst, G. K.: Adsorption of Influenza Virus on Cells of the Respiratory Tract, *J. Exper. Med.* 78: 99-109 (Aug.) 1943.

127. Hirst's discussion of these important experiments, which should be consulted in detail, contains the following paragraph: "While the data are meager as yet, it is tempting to formulate a tentative hypothesis as to the possible mechanism of the early stages of influenza virus infection of the respiratory cell. It may not be sufficient merely for an inhaled virus particle to come in contact with any point on a susceptible cell, and it may be necessary for it to become attached to a specific receptor substance to gain entrance. Before the virus can infect, it may also have to alter or destroy this receptor substance by means of an enzyme in order to pave the way for penetration and parasitism of that cell. Once the receptor substance is destroyed the virus becomes more firmly bound, parasitizes the cell, multiplies and again appears free in the lung, making possible spread of infection by contiguity. Since the close correlation has been demonstrated between the neutralizing and agglutinating-inhibiting power of various human sera, it may be that neutralization (in mice) consists mainly of covering over that portion of the virus which ordinarily attaches itself to the receptor substance."

THE NOBEL PRIZE AWARDS

Announcement from Stockholm indicates that the 1943 and 1944 Nobel prizes in physiology or medicine have been awarded to four investigators, all of whom are now in the United States and three of whom are Americans. The prize for 1939 was the last previously awarded and was offered to Gerhard Domagk, a German, for his discovery of the use of sulfanilamide in medicine. He subsequently informed the Nobel Prize Committee that the ban of the German government on the acceptance of Nobel prizes prevented him from accepting the award.

The 1943 award was made to Drs. Edward A. Doisy, professor of biochemistry at the St. Louis University School of Medicine, and Henrik Dam of Copenhagen, who is now assistant professor of biochemistry at the University of Rochester School of Medicine and Dentistry, Rochester, N. Y., for their fundamental investigations on the chemical nature of vitamin K. Editorials in THE JOURNAL have repeatedly discussed this contribution and have often emphasized its significance. Vitamin K was discovered and named by Dr. Dam in 1935, when he observed in newly hatched chicks a fatal hemorrhagic diathesis which could be cured or prevented by the administration of a nonsaponifiable nonsterol fraction of hog liver or alfalfa. Later it was observed that the delayed clotting time of the blood was due to a low prothrombin content. The work of Doisy showed that there are at least two naturally occurring substances which have similar physiologic properties, and they are now called vitamins K₁ and K₂. These investigations have led to the use of vitamin K in obstructive jaundice, in which it has been shown to have an extraordinary protective effect against hemorrhages. It is also used in the hemorrhagic states associated with ulcerative colitis, sprue, celiac disease and the hemorrhagic state associated with primary hepatic disease and in the treatment of the physiologic hypoprothrombinemia of the newborn which exists during the first week of life. It is now almost routine to give this vitamin by injection to a woman during labor so that the newborn infant

will have a normal amount of prothrombin in the circulating blood. The drug may also be given directly to the newborn infant.

The 1944 award was presented to Drs. Joseph Erlanger, professor of physiology at Washington University School of Medicine, St. Louis, and Herbert Spencer Gasser, director of the Rockefeller Institute, New York, for their studies on the function of individual nerves. Their contributions to a knowledge of the electrophysiology of nerves using the cathode ray oscillograph have yielded information of great importance in understanding the mechanism of action of the nerves. Fundamentally, Gasser and Erlanger showed that the speed of conduction is correlated with the size of the axon. The greater the diameter of the whole axon, the greater the speed of conduction. The largest fibers are motor and are therefore stimulated more easily and carry the impulse with greater speed. For instance, the sensory roots contain large, medium and fine fibers and in the order given carry the sensations of touch, pressure, pain and temperature. Studies made on conduction indicate, for instance, that cocaine will abolish sensation in the order of pain, temperature and touch, while pressure will affect sensation in the reverse order.¹

This recognition of the contribution of the United States to medical research cannot but arouse a feeling of great pride in the physicians and in the research institutions of our country. The annual prizes are worth about \$29,000 and will be divided among the winners.

"PRINCIPLES OF A NATION-WIDE
HEALTH PROGRAM"

Last week some physicians in the United States received from the Committee on Research in Medical Economics of New York the galley proofs of a proposed pamphlet to be called "Principles of a Nation-Wide Health Program." The report comes with twenty-nine sponsors, who are said to have had several meetings and conferences. The expenses of the conferences and the publication were met by gifts contributed for this purpose. The physicians who participated in this planning conference included Ernst P. Boas, Allan M. Butler, Hugh Cabot, Nathaniel W. Faxon, Channing Frothingham, Alan Gregg, John P. Peters and Kingsley Roberts. Most of these names are familiar to the medical profession through their association with what was once known as the Committee of 400. Their points of view have been widely publicized again and again.

Physiol. 80: 522, 1927; *The Role of Fiber Size in the Establishment of a Nerve Block by Pressure or Cocaine*, Am. J. Physiol. 88: 581, 1929; *Electrical Signs of Nervous Activity*, London, Oxford University Press, 1937. Gasser, H. S.: *The Control of Excitation in the Nervous System*, Harvey Lectures 22: 169, 1937. Gasser, H. S., Erlanger, J.; Bronk, D. W.; Lorente de No, R., and Forbes, A.: *Symposium on the Synapse*, J. Neurophysiol. 2: 41, 1939.

Among those who are not physicians and who apparently had leadership in the movement were I. S. Falk, attached to the Social Security Board; Michael M. Davis, who to all intents and purposes is the Committee on Research in Medical Economics; C.-E. A. Winslow of New Haven, Conn., and Edwin E. Witte of Madison, Wis. Finally there were several physicians of the U. S. Public Health Service and several teachers of economics. Without reading the "Principles of a Nation-Wide Health Program" developed by this group, any well informed physician would know the nature of the recommendations.

The purpose of the conference was the formulation of the elements of a nationwide health program which would unite the views of physicians, economists and administrators. The physicians in this conference do not represent the opinions of any considerable number of physicians in this country. Individually some of them apparently have a following of a few hundred doctors.

This report, which bears throughout innumerable indications of the authorship of Michael Davis, is replete with plausible aphorisms regarding medical care such as have marked such "literature" since Michael Davis became associated with the Rosenwald Fund. The Committee on Research in Medical Economics was established when he separated from the Rosenwald Fund. At that time a final grant of some \$135,000 was apparently made so he could carry on his activities under his own auspices; this sum has apparently been supplemented from time to time with small grants from other foundations. The report attacks plans of medical care which are limited to hospitalization, surgery or catastrophic illness only and also plans which provide cash payments. It calls for association of the health program with a broad system of social security.

The report asserts that a nationwide health program demands that (1) comprehensive medical services and facilities shall be physically and financially available to all the people, (2) these services shall be so organized and supplied as to be scientifically efficient and as economical in cost as is consistent with quality, (3) the services shall be adequately and securely financed and (4) professional opportunities shall be improved and adequate income assured the persons and institutions furnishing service. These are the objectives to which practically every intelligent person will subscribe. It is then stated that the health program should be a national system with decentralized administration of services and that it should cover the entire population, but that those who wish to purchase medical care outside the national health system should be free to do so. Compulsory sickness insurance is advocated with the statement "The chief support of a nationwide system of medical care should be contributory insurance required by law, with the amounts of

payment from employees, employers and self-employed persons related to the earnings of the contributors, combined with support from general taxation." General tax funds are to be secured in order to aid new or improved hospitals and health centers, particularly in rural areas, the further extension of full time public health departments and the provision or improvement of medical services to those dependent and other persons not directly covered by the insurance system, such as the chronically ill, the disabled and the aged. Free choice of physician is mentioned as a necessity, also the right of the physician to accept or reject patients and the right to participate or not to participate in the system. The voluntary hospitals, it is said, would remain as independent agencies which would make individual or group contracts for furnishing services under the national program and which would retain full responsibility for their own administration. Hospitals would retain responsibility for their administration, yet they could survive only by negotiating contracts with a governmental agency. The program proposes three methods of payment of physicians, including salary, capitation and (under certain conditions) fee for service, although it concludes that the use of the fee for service method should be discouraged.

The most important portion of this proposed program is the section devoted to the administrative organization. Here comes the statement that the national policy determining body for the national program should be representative of the chief groups of those who receive the service and of those who furnish it. The administrators of all professional and technical aspects of the program are to be qualified professional persons, the professional and the financial officials each having administrative authority in their respective fields. As might be anticipated, the proposals point again and again to the concept that the administrative control of medical services will be put in nonmedical hands.

Physicians who study this report are advised to consider particularly the next to the last paragraph. This reads:

There are numerous, important regulations which cannot be specified in a law. Some of these regulations may be national in application. Others will be designed for certain localities or will relate only to particular forms of service. These regulations must be worked out by the administrative authorities and when adopted have the force of law.

This paragraph represents the apotheosis of bureaucracy. Were the medical profession to agree to such a concept, it would be signing a blank check and turning it over to the nonmedical administrators for such disposition as they might care to make of the future of medicine.

Physicians who have followed the information made available through *THE JOURNAL* in recent months will

have noted the action taken in the International Labor Organization conference,¹ the action taken by the committee of the American Public Health Association² and now this report by Michael Davis's Committee on Research in Medical Economics. They should note that the same group has been active in all three places. They do not represent the medical profession of the United States. It is certainly questionable whether or not they represent any considerable number of people outside of themselves.

BACTERIOPHAGE ELECTRON MICROGRAPHS

Under the auspices of the Council on Pharmacy and Chemistry THE JOURNAL completes this week publication of a review of recent knowledge developed by use of the electron microscope. Already much of the practical value in the diagnosis and treatment of disease has been learned in this way.

Soon after the introduction of the electron microscope several European investigators¹ published micrographs showing the presence of minute "spermlike" particles in 'phage lysed bacterial cultures not present in 'phage free controls. More detailed studies of these presumptive "bacteriophagic sperms" have recently been reported by Luria² of the Guggenheim Foundation and Baylor³ of the University of Illinois. Luria photographed 3 coli bacteriophages. One of these had a uniformly opaque "head" 45 to 50 millimicrons in diameter to which was attached a "tail" about 150 millimicrons long and 10 to 15 millimicrons thick. The head of a second coli 'phage showed opaque and translucent areas, suggesting a nucleus. A third coli 'phage was apparently without a tail. One staphylococcus 'phage was about twice the size of the first coli 'phage in all dimensions, or eight times its volume. A second tailless 'phage acting against *Salmonella pullorum* is described by Baylor.

The particles thus made visible breed true in homologous bacterial cultures, they are never seen in 'phage free bacterial autolysates, and their number is always directly proportional to 'phage titer. The most suggestive part of these studies, however, are studies of the method of reaction between 'phage units and homologous bacterial cells. Usually within three minutes after bacteriophage has been added to a homologous bacterial culture practically all of the 'phage particles become adherent to the limiting membranes of the

bacterial cells. There is no evidence of a multiplication of the particles on the bacterial surfaces or of lytic action on the underlying parts of the bacterial cytoplasm. Luria's micrographs suggest that only one of the adherent 'phage particles is able to penetrate (or is drawn into) the bacterial cell. The other adherent particles are apparently excluded by a mechanism analogous to the exclusion of superfluous sperms by monospermatic ova. This suggests a closer genetic relationship between bacteria and homologous 'phage than previously assumed.

Following entrance of the single fertilizing 'phage unit there are local reductions in the opacity of the bacterial cytoplasm, accompanied by a capsular swelling, suggesting an increase in internal osmotic pressure. By the end of about twenty-five minutes the swelling and loss of opacity are usually complete. Rupture of the limiting membrane now takes place in one or more places. The excluded liquefied cell contents usually contain a hundred or more new 'phage particles, many of them attached to one another to form chains. The damaged or lacerated cell wall now remains as an almost invisible ghost.

This work has a suggestive bearing on current theories of virus antagonism. The suggestion that only one virus particle may enter an infected tissue cell, and that after entry it so alters the chemotactic balance as to exclude all other virus particles, is a plausible theory of epidemiologic interest. No adequate theory of the antagonism or mutual exclusion of different viruses had been previously suggested.

ARTERIOSCLEROSIS

The word arteriosclerosis is used for a variety of vascular diseases differing greatly in etiology and causative mechanism. The century old controversy with regard to the role of the various factors in the production of degenerative and sclerosing vascular lesions still continues.¹ The uncertainty and confusion interfere with the development of effective preventive and therapeutic measures. The problem has increasing medical, economic and social importance in view of the accelerated aging of the general population.²

Actually arteriosclerosis is not a normal sequel of aging and therefore as inescapable as gray hairs and wrinkles. In a current review of this subject Hueper³ has evaluated the available clinical, pathologic and experimental data. He divides the known exogenous

and endogenous causes of arteriosclerosis into four main groups according to their special causative mechanism: (1) hypotonic and hypertonic vascular agents, (2) hypotensive and hypertensive intravascular hydrostatic factors, (3) colloidal plasmatic disturbances and (4) hematic anoxemic agents. The fundamental mechanism common to all these agents, according to Hueper, is an impairment of the oxygenation and the nutrition of the vascular wall. However, only colloid plasmatic disturbances of lipoid or carbohydrate nature produce foam cell atheroma and atherosclerosis, while the other agents elicit edematous, fibrosing and hyaline intimal thickening. Medial degeneration and calcification are seen with all agents, and their occurrence depends in part on the intensity of the arteriosclerogenic action of a particular agent, in part on complicating factors.

Applying these concepts to prevention and therapy of arteriosclerosis, Hueper notes that proper consideration must be given in the choice of such procedures to their suitability in the individual case in view of the existing differences in the character of the causal agent, the type of causative mechanism and the anatomic character of the vascular reaction. Thus atheromatosis and atherosclerosis require preventive and therapeutic measures different from those indicated in combating the causal factors and anatomic lesions connected with vaso-tonic mechanisms. Similar considerations apply also to the selection of diagnostic procedures. The concepts advanced are provocative in many respects and should stimulate physicians as well as nutritionists and chemists to adopt a more comprehensive approach to the problem of arteriosclerosis.

Current Comment

THERAPY OF ADVANCED SHOCK

Many investigators hold that there is strong contraction of the arterioles and arteries in hemorrhagic and traumatic shock and that the use of vasoconstricting agents is contraindicated and harmful because it results in further decrease of blood to important organs. Recent observations raise serious doubts of the correctness of this assumption and its therapeutic implication. Chambers and his co-workers¹ noted that a vasopressor agent is present in the blood only in the primary phase of shock, while in the late and therapeutically most important stage a vasodepressor substance predominates. In experiments on dogs with sectioned aortic depressor and carotic sinus proceptor nerves Schafer² found that the hypertension did not elicit any shock syndrome. These results as well as observations in surgical practice do not lend support to the theory of a sympathico-adrenal hyperactivity in shock. The application of heat in shock may aggravate the condition apparently by

relaxing the peripheral vessels and thereby favoring hypotension. Cold, on the other hand, reduces the onset or severity of shock by peripheral constriction and reduction of the total vascular bed, making more blood available to internal organs. The validity of this reasoning is supported from the results obtained by Hueper and Ichniowski³ in dogs with severe and advanced histamine shock following a slow intravenous injection of a solution of hydrophilic colloid (methyl cellulose) and a cardiovasopressor agent (s-methylisothiourea). Similar good effects on terminal hemorrhagic shock in dogs were recently recorded by Kohlstaedt and Page⁴ by the consecutive administration of tuamine (2-amino heptane sulfate), a pressor amine, and blood. These results suggest that the combination of increased intravascular hydrostatic pressure and stimulation of the contractile cardiovascular tissue, which is anoxemically injured and therefore abnormally relaxed, may represent a rational therapeutic procedure in the management of advanced traumatic or hemorrhagic shock.

RECRUITMENT OF CIVILIAN PHYSICIANS FOR ARMY DISCONTINUED

Elsewhere in this issue appears the announcement by the War Department and by the War Manpower Commission that recruitment of civilian physicians for the Army has been discontinued. The Navy requires 3,000 additional officers at once. The Army is to fill its future requirements from the young men who complete their medical education and internships. There are now 47,500 physicians on duty in the Army, including those serving with the Veterans Administration, and some 13,000 in the Navy. Three hundred additional physicians are needed for the Coast Guard. During the war emergency physicians from the Army Medical Department and the U. S. Naval Reserve will be assigned to the Veterans Administration to meet the needs of care of the veterans. In the meantime it will become necessary for the Veterans Administration to recruit additional physicians in large numbers to meet the needs of that agency when it is no longer possible to supply physicians through the armed forces.

RABIES IN NEW YORK CITY

Because of the spread of canine rabies from the borough of the Bronx to the rest of New York City the board of health has recently extended the antirabies quarantine on dogs to the entire city. One New York woman who was bitten by her pet has already died from this disease. The police department has been directed to issue court summonses to owners of dogs who allow their animals to run at large without a leash. A rigid system of quarantine is now necessary, it has been announced. Rabies in dogs and some wild animals is now so widespread that concerted nationwide efforts at its elimination through quarantine are needed.

MEDICINE AND THE WAR

ARMY

NEW ARMY STATEMENT ON REQUIREMENT AND USE OF PHYSICIANS

The requirements of the Surgeon General to maintain the established strength of Medical Corps officers on active duty will be met through the appointment of medical ASTP trainees and medical students holding inactive commissions in the Medical Administrative Corps and by calling to active duty Medical Corps officers who are on inactive status for further training as interns, junior residents or senior residents at nonmilitary hospitals. Accordingly, appointments in the Medical Corps, Army of the United States, will not be made direct from civil life except for assignment to active duty with the Veterans Administration.

All appointments resulting from applications processed in accordance with this directive will be in the Medical Corps, A. U. S., for assignment to duty with the Veterans Administration only. Every effort must be made to persuade candidates whose applications are processed under these instructions to accept this appointment.

Recalcitrant physicians, including interns and residents, will not be reported to Selective Service.

Qualified candidates who of their own volition may apply for commission in the Medical Corps and who cannot be processed under these instructions will be advised that a great need exists within the Navy and Public Health Service and will be urged to contact the appropriate offices for information regarding these services.

NEUROPSYCHIATRY FOR GENERAL MEDICAL OFFICER

According to the Technical Bulletin of Medicine No. 94, issued by the War Department recently, every medical officer, regardless of his mission, whether battalion surgeon, ward officer, flight surgeon or dispensary physician, is confronted with psychiatric problems. There is an inadequate number of psychiatrists, and, furthermore, not only must the average medical officer do most of the minor psychiatry in the Army, but in some instances he may also be forced by circumstances to do major psychiatry. Psychiatric treatment, like surgical treatment, is most effective when carried out early, promptly and skilfully. Consequently, some of the best psychiatry will be done outside the hospital in such places as the dispensary, the consultation service, the battalion aid station, the clearing station and the air strip. Because most medical officers have inadequate training in this field, the suggestions in this bulletin are presented as a general guide.

SHORTAGE OF NURSES IN THE ARMY

Major Gen. Norman T. Kirk, Surgeon General of the Army, announced recently that there is a critical shortage of nurses in the Army and that there has been a disappointing response to the call for 10,000 additional nurses. Only 500 applied out of the 4,000 expected during September. Army nurses now number about 40,000, the number in the United States having been reduced to about 13,000. About 4,000 of these are assigned to the Air Forces.

TRENCH FOOT

The War Department recently issued a change in regulations governing treatment for trench foot from that given in the Technical Bulletin of Medicine No. 81, issued August 4, as follows:

Treatment. b. Definitive treatment. (1) Patients should be kept in bed, with the affected parts on a horizontal level with or elevated on pillows only slightly above heart level, and protected from external pressure either by complete

exposure or by means of a cradle. Elevation of the extremities should be done only if there is no evidence of inadequate circulation, that is, incipient gangrene; otherwise they should be maintained on a horizontal level. The period of bed rest is determined by degree and rate of subsidence of edema for this form of treatment.

ARMY AWARDS AND COMMENDATIONS

Captain Hershell B. Murray

Capt. Hershell B. Murray, formerly of West Liberty, Ky., recently received a letter of commendation from Brig. Gen. Emer Yeager for his exemplary work performed by his field hospital unit in the South Pacific war zone. The letter of commendation read, in part, "Please express to the officers, nurses and enlisted men of the 5th Field Hospital my regards and appreciation of the manner in which this unit functioned since entering this base. During the period July 13 to August 3, 1944, under adverse conditions, the hospital was constructed and operated. A great many more patients than normal for such a unit received the best possible care. It is the opinion of the surgeon of the headquarters that the entire operation was the finest done by any hospital seen in this theater. Such performance reflects the highest type training, morale and discipline." Dr. Murray graduated from the University of Louisville School of Medicine in 1932 and entered the service Sept. 13, 1942.

Major Samuel M. Klein

Major Samuel M. Klein, formerly of Jackson Heights, N. Y., was recently cited by Lieut. Gen. Mark W. Clark for "conspicuous coolness" under fire in Italy. The citation states that at Anzio last January the doctor ignored "bombing, shell fire and falling flak by continuing to perform his duties of [treating] the wounded. His selfless devotion to duty aided in saving lives. His performance reflects the high tradition of the Medical Corps." Dr. Klein served in Africa and with the first invasion of Sicily, Salerno and Anzio and now is stationed at a base hospital near Rome. Dr. Klein graduated from New York University College of Medicine, New York, in 1920. Before joining the army in August 1942 Dr. Klein was president of the Long Island City Medical Society.

Captain Bertram E. Sprofskin

The Soldier's Medal was recently awarded to Capt. Bertram E. Sprofskin, formerly of Nashville, Tenn., for heroism in making several spectacular rescues in the Southwest Pacific. The citation stated that he entered the "high and choppy seas" to bring the first soldier in from about 150 yards. Then "despite exhaustion from the first rescue," he swam to the aid of another struggling soldier, who was about 100 yards at sea and 150 yards east of him. "The action of Captain Sprofskin on this occasion undoubtedly saved the lives of both men and reflects great credit on himself and the military service." Dr. Sprofskin graduated from Vanderbilt University School of Medicine, Nashville, in 1942 and entered the service July 30, 1943.

Major Solomon Rosokoff

The Bronze Star was recently awarded to Major Solomon Rosokoff, formerly of Tonawanda, N. Y., and now an executive officer of an armored medical battalion in France. The citation read in part "He has actively coordinated much of the evacuation of the wounded in his division by liaison. In order to maintain contact with these units, Major Rosokoff subjected himself to enemy artillery, small arms fire and aerial bombardment without regard to personal safety. . . . Treatment of the wounded was reduced to a minimum, thereby saving lives." Dr. Rosokoff graduated from the University of Buffalo School of Medicine in 1935 and has been in the service for four years.

PROCUREMENT AND ASSIGNMENT SERVICE FOR PHYSICIANS, DENTISTS AND VETERINARIANS

ARMY MEDICAL DEPARTMENT DISCONTINUES RECRUITMENT OF CIVILIAN PHYSICIANS

Paul V. McNutt, chairman of the War Manpower Commission announces that he has been informed by the War Department that recruitment of civilian physicians for the Army has been discontinued. At the same time he announces that recruitment for the Navy must continue, since it has urgent need for approximately 3,000 additional medical officers. The U. S. Public Health Service and the Veterans Administration are also continuing to recruit physicians, Mr. McNutt said.

Vice Admiral Ross T. McIntire, chief of the Bureau of Medicine and Surgery, U. S. Navy, informed Mr. McNutt that personnel expansion and intensification of operations in the Pacific have precipitated a grave shortage of medical officers.

"With less than 13,000 medical officers on active duty in the Navy the procurement of at least 3,000 more as soon as possible is imperative," said Admiral McIntire. "Even this figure will not meet actual needs but would ease the emergency that now exists, physicians and surgeons whose availability has been or may hereafter be certified by the Procurement and Assignment Service WAC, should lose no time in obtaining particulars for commissions in the Navy Medical Corps by communicating with their nearest office of Naval Officer Procurement."

Mr. McNutt said he had been informed that the Army will fill its future requirements for military physicians from sources now available to the Army and thereafter will not require certification of availability of additional physicians from the Procurement and Assignment Service of the War Manpower Commission. There are now about 47,500 physicians on duty as medical corps officers of the Army. This probably includes those serving with the Veterans Administration and other governmental agencies to which the Army Medical Corps assigns its medical corps officers.

Mr. McNutt said that there are at present roughly 60,000 physicians in the armed forces and the Veterans Administra-

tion. The total number of physicians in the armed forces represents approximately 40 per cent of the active medical profession of the United States.

In addition to the 3,000 medical officers needed at present by the Navy, the Public Health Service has need for approximately 300 for the U. S. Coast Guard and other agencies.

In informing Mr. McNutt of the termination of the Army recruiting of physicians except for the occasional specialist Major Gen. Norman T. Kirk, Surgeon General of the Army, said "The large number of physicians now in the Army volunteered for commissions without regard for their personal interests. The U. S. Army Medical Department is appreciative of the fine service they have given. Their removal from their usual practice also represents a sacrifice on the part of all civilians, who have had to get along with less medical care than they obtained in peacetime."

The Veterans Administration has, and will continue throughout the duration of the war emergency to have, assigned to it medical officers in the Army and the U. S. Naval Reserve to care for the needs of the casualties in its charge, the War Manpower Commission said. Doctors whose applications are at present in process for appointment in the Army Medical Corps will be considered for appointment and assignment to duty with the Veterans Administration, the War Manpower Commission statement added.

Mr. McNutt said that the War Manpower Commission joins with the directing board of its Procurement and Assignment Service and the War Department and the Office of the Surgeon General in expressing appreciation of the sacrifice involved in cooperation that was necessary on the part of physicians and the public before the Army reached its present level of medical personnel.

Mr. McNutt also expressed the hope that additional civilian physicians will respond to the Navy's appeal for more doctors to apply for commissions. The needs of the U. S. Public Health Service and the Veterans Administration he said although much smaller than those of the Navy are nevertheless important.

MISCELLANEOUS

HOSPITALS NEEDING INTERNS AND RESIDENTS

The following hospitals have indicated to the Council on Medical Education and Hospitals that they have not completed their house staff quota allotted by the Procurement and Assignment Service.

(Continuation of list in THE JOURNAL, October 21, page 504.)

CALIFORNIA

St. Joseph's Hospital, San Francisco. Capacity, 289 admissions. 7,218. Sister M. Raymond, Superior (intern).

CONNECTICUT

Hospital of St. Raphael, New Haven. Capacity, 400 admissions, 7,980. Sister Rose Alexis, Director (interns).
Waterbury Hospital, Waterbury. Capacity, 372 admissions. 8,144. Miss Andr. E. Creer, R.N., Superintendent (5 interns, 1 resident, July 1, 1945).

IOWA

Iowa Methodist Hospital, Des Moines. Capacity, 270 admissions. 8,000. Mr. R. A. Nettleton, Administrator (intern, July 1, 1945).

LOUISIANA

North Louisiana Sanitarium, Shreveport. Capacity, 121 admissions. 500. Mr. Herman I. Herold, Administrator (intern).

NEW HAMPSHIRE

Sacred Heart Hospital, Manchester. Capacity, 163 admissions. 2,561. Sister Mary Bernadus, R.N., Superintendent (mixed residents).

NEW JERSEY

St. Joseph Hospital, Paterson. Capacity, 460 admissions. 7,234. Sister Anna Rita, R.N., Superintendent (4 interns, 1945).

NEW YORK

Our Lady of Victory Hospital, Tuckahoe. Capacity, 185 admissions. 4,143. Sister M. Batholae, Superintendent (2 interns, Jan. 1, 1945).

OHIO

Springfield City Hospital, Springfield. Capacity, 309 admissions. 6,917. Mr. F. E. Kasser, Executive Director (2 interns).

TENNESSEE

Knoxville General Hospital, Knoxville. Capacity, 325 admissions. 7,714. Mr. T. H. Haynes, Superintendent (3 interns, April 1, 1945).

WASHINGTON

Providence Hospital, Seattle. Capacity, 434 admissions. 15,858. Sister M. Bernadine, R.N., Superintendent (2 interns, 2 residents).

WEST VIRGINIA

Charleston General Hospital, Charleston. Capacity, 380 admissions. 10,200. Dr. John E. Cannaday, Director (junior resident—surgical).

WARTIME GRADUATE MEDICAL MEETINGS

The following subjects and speakers for Wartime Graduate Medical Meetings have just been announced.

Deshon General Hospital, Butler, Pa. The Deep and Superficial Mycoses, Major H. H. Sawicki, November 9, Psychoneurosis, Capt. Peter H. Knapp, November 16.

U. S. Naval Hospital, Great Lakes, Ill. The Management of Acute Respiratory Obstructions, Dr. Paul H. Holinger, November 8, Rest, Dr. Don C. Sutton, November 21.

Camp McCoy, Wis. Malignancies in the Army Age Group, Dr. Gorton Ritchie, November 15, Endocrinology, Dr. Elmer L. Seeringhaus, November 29, Gallbladder and Liver Disease, Dr. Erwin R. Schmidt, November 29.

Tuberculosis League.—The thirty-eighth annual meeting of the New Jersey Tuberculosis League was held at the Hotel Stacy-Trent, Trenton, October 17. Among the speakers participating in a panel discussion on "Problems of Developing a Program for the Discovery and Prevention of Tuberculosis in Industry" were Dr. Leopold Brahdy, New York, Louis Horowitz, area director, War Relief Committee, Congress of Industrial Organizations, Dr. A. Joseph Hughes, Camden, and Dr. John F. Johnson, Trenton. In a session devoted to "Forty Years of Progress in Stamping Out Tuberculosis" the speakers included Dr. Charles J. Hatfield, Philadelphia; Louis I. Dublin, Ph.D., New York; Dr. Frederick H. C. Heise, Trudeau, N. Y., and Clyde R. Miller, Ph.D., New York.

NEW YORK

Graduate Lecture.—Dr. John G. Fred Hiss, professor of clinical medicine, Syracuse University College of Medicine, Syracuse, will address the Erie County Medical Society in Buffalo, November 28, on "Common Errors in the Diagnosis of Heart Disease, with Special Reference to Rheumatic Heart Disease."

Personal.—At the recent graduation exercises of the New York Medical College, Flower and Fifth Avenue Hospitals a "gold diploma" signifying fifty years of service in the practice of medicine was presented to Dr. William L. Love, Patchogue. —Dr. Elias W. Young has been appointed substitute village health officer of Goshen, succeeding the late Dr. Ralph L. McGeoch, who held the position during the absence of Dr. Nathaniel T. Keys.

New York City

Bailey B. Burritt Retires.—Bailey B. Burritt, A.M., retired on November 1 as chairman of the executive council of the Community Service Society of New York under the group's retirement plan. He has served the society for thirty-one years. A newly created position of general director will be filled by Stanley P. Davies, Ph.D., executive director of the society since its formation by merger in 1939.

Artists Cooperate in Health Posters.—A special exhibit is on display at the Wilderstein Galleries showing the conception of famous artists on health education. The pictures and their captions were developed under the leadership of Madame Elsa Schiaparelli as chairman of a special committee on health posters with the assistance of the American Museum of Health. The posters are intended primarily for use in public health programs to be carried on in Europe after the war and in the meantime are available for reproduction and use in this country. One of the features of the exhibition is a poster on syphilis by Salvatore Dali; there are also health education studies by Vertes, Helion, Donati and Farbes.

Diabetes Clinical Society Organized.—The Clinical Society of the New York Diabetes Association has been organized with the following officers: Drs. John J. Weber, Brooklyn, chairman; Louis Bauman, New York, first vice chairman; Edmund L. Shlevin, Brooklyn, second vice chairman, and Harry G. Jacobi, New York, secretary-treasurer. The society is functioning under the auspices of the parent organization and is somewhat of an outgrowth of the clinics committee, which has now been dissolved. The society will consist of fellows, associate fellows and members. A carefully selected founding group of specialists in diabetes will constitute the nucleus of the fellowship; this group will formulate standards for subsequent admission to fellowship and associate fellowship and will be the sole body which votes in future fellows. The board of directors of the New York Diabetes Association wishes to establish a representative founding group from among the specialists in the five boroughs and has appointed a nominating committee to examine credentials and to make recommendations. The new society will take over the establishing of standards for diabetes clinics in New York City and the vicinity. It will aim to bring about general adoption of these standards and for this purpose will recommend to the parent organization certification of individual hospital clinics adequately meeting its prescribed standards, as well as withdrawal of certification on delinquency. It will initiate, conduct and publish statistical surveys on the basis of data derived from certified clinics. It will promote constructive relationships between physicians who are specialists in diabetes and representative physicians of allied medical specialties, such as ophthalmologists and surgeons, who will selectively be admitted to the fellowship. It will have contact with related technical groups such as dietitians, laboratory technicians, nurses and social workers through the "member" category. It will by close mutual association promote scientific understanding and

conquest of problems in the management of diabetes, especially as these are encountered in clinical practice. The inaugural meeting of the society was held at the University Club, October 26.

Mayor's Health Plan Launched.—The Health Insurance Plan of Greater New York, proposed by Mayor Fiorello La Guardia this year, was informally organized at a meeting on October 19. Temporary officers were chosen and the honorary title of Founder conferred on the mayor. Among the temporary officers are Dr. Willard C. Rappleye, chairman, dean of the Columbia University College of Physicians and Surgeons, and Mr. Winslow Carlton, secretary; Dr. John J. Wittmer and Matthew Woll, labor leader, are among the vice presidents. About \$200,000 is now available for underwriting the program, of which \$150,000 is pledged by the New York Foundation and \$25,000 by the Albert and Mary Lasker Foundation. The plan aims to provide comprehensive medical and surgical services at moderate cost to all persons living or working in New York and earning up to \$5,000 a year (*THE JOURNAL*, May 13, p. 161). The New York Times in reporting the meeting stated that one of the main tasks of the directors would be to obtain the cooperation of the five local county medical societies. These groups, while endorsing the plan in principle, are opposed to the \$5,000 income ceiling for eligibles, preferring a ceiling of \$2,500 or, at most, \$3,000. It will be up to the directors, it was said, to convince the organized medical groups that a \$5,000 ceiling is needed to obtain group enrolments that will include section heads, foremen and other employees in supervisory positions. Another important job set for the directors by the mayor is to convince the medical societies that "teamwork medicine" should be part of the program. The mayor cited the advantages of group medicine as practiced in other cities. Coverage would also extend to members of their families under 18 years of age. The plan cannot begin to function, it was said, until the state insurance department has approved the financial setup.

Another Diploma Mill.—George William Manus, 24 years old, was taken into custody October 13 charged with operating a diploma mill in a two room suite at 103 Park Avenue which specialized in doctorates, the New York *Herald Tribune* reported. He was arraigned before Judge Frederick L. Hakenburg in special sessions for alleged violations of the state education and penal laws and was held in \$5,000 bail for a hearing that was to be held October 16. An investigation by the court disclosed that Manus had issued some 4,000 "degrees" for fees running from \$450 to \$800. From letter-heads and documents found in the office, police were reported to have said that Manus represented himself as a physician with an M.D. degree from White Cross Medical College of the University of Physicians and Surgeons of Southern California. He also called himself executive vice dean and treasurer of the New York College of Psychiatry. Both institutions were allegedly mythical. "His pet institutions" for which he issued his diplomas were called "Extension Branch of Los Angeles University, College of Psychiatry," and the "Golden State University of Los Angeles." The former is said to be nonexistent and the latter is the outgrowth of the Eldridge Drugless Colleges incorporated in California in 1922. A report on the school published in the *Federation Bulletin* in May 1940, page 151, stated that all schools in the United States should be aware of the fact that degrees given by the schools are of "diploma mill" worth. The newspaper reported that the courses of study offered by Manus included hypnotic, painless and drugless childbirth, prenatal suggestion, instantaneous hypnosis, reflex therapy (described as a method for growing hair on bald heads), practical and applied psychology, suggestion and autosuggestion, psychological somnotherapy, suggestive therapeutics, color therapy, vibro therapy, chemical psychology and chemical psychotherapy, advanced esoterics and metaphysics. His specialty was the solicitation of chiropractors as postgraduate students in "psychological healing" in all its branches, leading to such degrees as doctorate of philosophy in psychology for a fee of \$500, doctorate of science for a fee of \$800, formerly \$1,000, and doctorate of psychotherapy for a fee of \$450. The New York County Grand Jury handed down an information against Manus on October 10 charging him with violations of section 66 of the state education law in that his "college" functioned without having been chartered by the state board of regents; conducting business under an assumed name without having filed a certificate with the county clerk; using the title "Doctor" in connection with public health matters without legal authorization in violation of the educational law, and issuance of descriptive material implying that his institution was a school of medicine, without sanction of the board of regents.

NORTH CAROLINA

New Professor of Pharmacology.—Dr. Arnold J. Lehman, associate professor of pharmacology, Wayne University College of Medicine, Detroit, has been appointed professor of pharmacology at the University of North Carolina School of Medicine, Chapel Hill. Dr. Lehman graduated at Stanford University School of Medicine, San Francisco, in 1936.

Changes in Health Personnel.—Dr. Greene L. Rea, who has been associated with the public health department in Charlotte for twenty-three years, was not to be assistant health officer after October 1, with the abolition of this position in the department. The decision to discontinue the position was reached during a recent reorganization of the health department under the direction of Dr. William R. Cameron.—Dr. Oscar David Garvin, health officer of Richmond and Scotland counties, has been appointed to a similar position in Chatham, Orange and Person counties to succeed Dr. William P. Richardson, Chapel Hill, who resigned to become a district director in the division of local administration of the state board of health, it is reported.

OHIO

Personal.—Dr. William E. Mishler, Cleveland, has been appointed chief surgeon of the Erie Railroad to succeed Dr. James Frank Dinnen, who is retiring because of ill health. Dr. Dinnen has been associated with the Erie Company since 1927; he had been assistant chief surgeon of the Nickel Plate Road for nineteen years assisting his father, who had been chief surgeon there since 1881, the *Cleveland Plain Dealer* reported.

Torald Sollmann Honored.—On September 25 Dr. Torald H. Sollmann, dean emeritus and professor emeritus of pharmacology and materia medica, Western Reserve University School of Medicine, was guest of honor at a dinner and presented with a silver plaque in recognition of his distinguished services. Winfred G. Leutner, LL.D., president of Western Reserve University, was toastmaster of the affair, which was sponsored by the faculty and alumni of the medical school. Dr. Sollmann, who had been associated with the school for nearly fifty years, is chairman of the Council on Pharmacy and Chemistry of the American Medical Association.

Broadcast in Health.—The Cleveland Health Museum, in cooperation with the Academy of Medicine of Cleveland and the Cleveland Dental Society, has resumed its radio programs over station WGAR. The series, which opened October 3 with a talk by J. V. Gentilly, D.D.S., and Dr. Gerald B. Hurd, on "A Tooth for Every Baby?" includes:

- Dr. Robert F. Parker, Penicillin, October 10.
- Ralph E. Creig, D.D.S., Your Child's Teeth, October 17.
- Dr. Horace E. Mitchell, Lakewood, Foreign Bodies in Food and Air Passages, October 24.
- C. C. Buckis, D.D.S., and Thomas F. Healy, D.D.S., Those Six Year Molars, October 31.
- Dr. Middleton H. Lambricht, Warning Signs of Cancer, November 7.
- Dr. Howard Lester Taylor, The Health Museum, November 14.
- Dr. Charles E. Kinney, To Protect Your Child's Hearing, November 21.
- Leon E. Newman, D.D.S., and William C. Stillson, D.D.S., Teeth of the Teen Age, November 28.

Medical Library Observes Fiftieth Anniversary.—The Cleveland Medical Library Association will celebrate its fiftieth anniversary, November 26-27. On the first day the library will be open for public inspection and Dr. Normand L. Hoerr, professor of anatomy, Western Reserve University School of Medicine, Cleveland, will deliver an address entitled "The Forgotten Man in Medical Education." A jubilee banquet will be held the second evening at which members of the library association will be hosts to invited civic leaders, educators, librarians and honorary consultants to the Army Medical Library. As a feature of the anniversary the association is planning the publication of a catalogue of the famous Niclaus Pol Library, of which the Cleveland Medical Library possesses the largest nucleus. The project is under the direct supervision of Dr. Max E. Fisch, curator of incunabula in the Army Medical Library.

OREGON

Medical Students Recommended for Membership.—At the recent annual meeting of the house of delegates of the Oregon State Medical Society it was voted to recommend to the council that a membership for medical students be created. The president of the society was also authorized to apprise Governor Earl Snell that the establishment of a university hospital at the University of Oregon Medical School, Portland, for patients on the indigent level was favorably considered. A

questionnaire seeking the profession's reaction to the proposal, which was issued by the dean of the medical school, states that the project was being planned to improve facilities for teaching medical students and "to provide a diagnostic service for doctors of the state for patients on the indigent level."

Physicians in the Legislature.—*Northwest Medicine* reports the following physicians as candidates in the Oregon legislature:

Dr. Ferdinand H. Dammasch of Multnomah County, a past president of the Multnomah County Medical Society, who was a member of the joint ways and means committee and chairman of the house committee on medicine, pharmacy and dentistry at the 1943 session, is again a candidate in the November election. Dr. Dammasch also served in the 1933 session.

Dr. William T. Johnson of Benton County, former president of the Oregon State Medical Society, is also a candidate for the house.

Dr. James A. Best of Umatilla County, holdover senator, is one of the veteran members of the senate, having served in the 1935, 1937, 1939, 1941 and 1943 sessions. He also served as representative in the 1933 session.

Dr. Joel C. Booth of Linn County, a past president of Central Willamette Medical Society, is also a holdover senator. Dr. Booth is a senior senator with service in the 1931, 1933, 1939, 1941 and 1943 sessions.

Dr. William A. Moser of Josephine County is a new candidate for the senate.

PENNSYLVANIA

Special Society Election.—Dr. Michael J. Penta was installed as president of the Reading Eye, Ear, Nose and Throat Society at its recent meeting in Reading. Other officers include Drs. Roland M. Brickbauer, first vice president, Isaac B. High, second vice president and president-elect, Harold L. Strause, treasurer, and Paul C. Craig, secretary.

Philadelphia

Annual Dinner of Resident Physicians.—The fifty-eighth annual dinner of the Association of Ex-Resident and Resident Physicians of the Philadelphia General Hospital will be held on December 5 at the Bellevue-Stratford Hotel, with Dr. George Wilson presiding as toastmaster. Ex-residents who do not receive notices of the dinner are requested to send their correct addresses to the secretary, Dr. Robert C. McElroy, 133 South 36th Street, Philadelphia 4.

TEXAS

Auxiliary Library Endowment Fund.—The Woman's Auxiliary library endowment fund was established September 18, when a check for \$1,000 was received in the office of the State Medical Association of Texas from the treasurer of the auxiliary. The donors of this, the first endowment fund of the auxiliary, are Mr. and Mrs. G. A. Ray, Pettus, who established this fund in memory of their daughter, Romayne Ray, who died Sept. 12, 1941. The fund is to be known as "The Romayne Ray Memorial Fund."

Personal.—J. Allen Scott, Sc.D., associate professor of epidemiology and medical statistics at the University of Texas School of Medicine, Galveston, is participating in the organization and work of a parasitology survey in the Amazon area at Belem, Brazil, under the auspices of the Rockefeller Foundation and the Office of the Coordinator of Inter-American Affairs. He will return to his duties at Galveston in November.—Dr. Julius C. Davis, Rule, has been appointed a member of the state board of health to succeed Dr. Samuel E. Thompson, Kerrville, resigned.

State Surgeons Choose Officers.—Dr. Samuel D. Weaver, Dallas, was elected president of the Texas Surgical Society, during its meeting in Galveston, October 2-3. Other officers include Drs. Jared E. Clarke, Houston, and George R. Enloe, Fort Worth, vice presidents; Walter G. Stuck, San Antonio, secretary, and Elbert Dunlap, Dallas, treasurer. Among the speakers at the meeting included:

- Dr. John W. Duckett, Dallas, Surgical Treatment of Tumors of the Liver.
- Dr. Enloe, Adenoma of Pancreatitis with Hyperinsulinism.
- Dr. Johnson Peyton Barnes, Houston, A Simple, Safe, Efficient Method of End to End or End to Side Intestinal Anastomosis.
- Dr. George V. Brindley, Temple, Presacral Tumors.
- Dr. George W. N. Eggers, Galveston, Chronic Dislocation of the Metacarpal of the Thumb.
- Dr. Frank C. Beall, Fort Worth, Deficient Fixation of the Right Colon.
- Dr. Marcos Fernan-Nunez, Milwaukee, Tropical Surgery.
- Capt. Stirling E. Russ and Capt. John S. Gaynor, M. C., Spontaneous Rupture of the Spleen.

The second day's program was devoted to clinical sessions. Features of the meeting included a talk by Stewart H. Evans, Galveston, British vice consul (honorary), entitled "A Clipper Trip to England" and an exhibit of drawings, sketches and etchings by Charles M. Pomerat, Ph.D., professor of anatomy, University of Texas Medical Branch, Galveston.

"Magnetic Ray Belt Maker" Fined.—Dr. Frank B. Moran, Dallas, who graduated at the University of Michigan Department of Medicine and Surgery, Ann Arbor, in 1894, was sentenced to ten days in jail and fined \$750 recently when a ruling was handed down that the physician had violated an injunction issued by the court in 1942 against transporting in interstate commerce his "magnetic ray belt," the *Texas State Journal of Medicine* reported. The belt is said to be made and sold by the Magnetic Ray Company, reputedly owned by Dr. Moran. The injunction was granted on petition of the government on the ground that the belt was mislabeled, it was stated.

VIRGINIA

Personal.—Dr. William A. Browne, city health officer of Alexandria, has been appointed epidemiologist of Richmond effective October 1. Dr. Browne held the Richmond position from 1935 to 1940. He once held a similar position in the New York City health department. He carried on a survey of scarlet fever in Richmond under the auspices of the Rockefeller Foundation, it is reported.

Faculty Changes at College of Virginia.—A department of physical medicine has been created under a recent grant by the Baruch Committee on Physical Medicine to the Medical College of Virginia, Richmond. Dr. Frances A. Hellebrandt, associate professor of physiology, University of Wisconsin Medical School, Madison, has been named professor of physical medicine, effective October 1, and Dr. Ernst Fischer, associate professor of physiology at the college, has been transferred from the department of physiology to the department of physical medicine with the rank of professor of physical medicine. Robert W. Ramsey, Ph.D., of the University of Rochester School of Medicine and Dentistry, Rochester, N. Y., has been named associate professor of physiology.

WASHINGTON

Industrial Hygiene Division Named Information Center in New Program.—The industrial hygiene division of the Washington State Department of Health was selected as an information center in a new cooperative industrial program in the state. The program was launched at a recent meeting in Seattle sponsored by the Seattle Safety Council and attended by representatives from labor, industry, government agencies and the medical profession. To avoid overlapping in a concentrated industrial health program, committees were appointed and industrial health problems were broken down into eight brackets: nutrition, safety, sanitation, occupational diseases, venereal disease, tuberculosis and other communicable diseases and plant medical facilities, including medical, dental, nursing and first aid activities. The industrial hygiene division of the state health department will function as an information bureau by referring each problem that comes to it from industry, labor or others to the appropriate committee, which in turn will decide where the responsibility lies under the coordinated program. According to *Northwest Medicine* it is believed that this service through the information bureau and the permanent committees will reduce confusion due to duplicated effort, overlapping activity and conflicting recommendations. Agencies cooperating in the program include the Committee on Congested Production Areas, King County Health Department, National Committee for the Conservation of Manpower in War Industries, Seattle City Health Department, Seattle Safety Council, Smaller War Plants Corporation, state health department, State Department of Labor and Industries, State Nutrition Committee, U. S. Army, U. S. Bureau of Mines, U. S. Department of Labor, U. S. Maritime Commission, U. S. Navy, U. S. Public Health Service, War Food Administration, War Manpower Commission, War Production Board labor production division, War Production Board production drive, Washington State Social Hygiene Association and the Washington Tuberculosis Association.

GENERAL

Urology Award.—The American Urological Association offers an annual award "not to exceed \$500" for an essay (or essays) on the result of some specific clinical or laboratory research in urology. The amount of the prize is based on the merits of the work presented, and, if the committee on scientific research deems none of the offerings worthy, no award will be made. Competitors shall be limited to residents in urology in recognized hospitals and to urologists who have been in such specific practice for not more than five years.

All interested should write the secretary for full particulars. The selected essay (or essays) will appear on the program of the June 1945 meeting of the American Urological Association. Additional information may be obtained from the secretary, Dr. Thomas D. Moore, 899 Madison Avenue, Memphis, Tenn., who must receive competitive essays on or before March 15.

Association of American Medical Colleges.—Dr. John Walker Moore, Louisville, was chosen president-elect of the Association of American Medical Colleges during its annual meeting in Detroit, October 23-25, and Dr. Albert C. Furstenberg, Ann Arbor, Mich., was installed as president. Dr. William S. McElroy, Pittsburgh, was elected vice president and Drs. Fred C. Zapffe and Arthur C. Bachmeyer, both of Chicago, were reelected secretary and treasurer respectively. Drs. Walter A. Bloedorn, Washington, D. C., and Wilburt C. Davison, Durham, N. C., were chosen members of the executive council of the association, succeeding Drs. Willard C. Rappleye, New York, and Russell H. Oppenheimer, Atlanta, Ga., whose terms expired. The 1945 session will be in New Orleans, October 29-31.

Special Society Elections.—Dr. Alan C. Woods, Baltimore, was named president-elect of the American Academy of Ophthalmology and Otolaryngology at its annual meeting in Chicago, October 12, and Dr. Gordon B. New, Rochester, Minn., was inducted into the presidency. New vice presidents include Drs. Edmund B. Spaeth, Philadelphia, William H. Johnston, Santa Barbara, Calif., and Major Brittain F. Payne, M. C. The next annual meeting will be held at the Palmer House, Chicago, Oct. 7-11, 1945.—Dr. William Bates, Philadelphia, was named president-elect of the United States chapter of the International College of Surgeons at its annual meeting in Philadelphia, October 4, and Dr. Rudolph Jaeger, Philadelphia, was inducted into the presidency. Other officers include Major Charles H. Arnold, M. C., secretary, and Dr. Benjamin I. Golden, Elkins, W. Va., treasurer. It was announced during the meeting that the international headquarters would be transferred from Geneva, Switzerland, to New York.

Courses for Orthopedic Surgeons.—The American Academy of Orthopaedic Surgeons has prepared a series of instructional courses to be presented at its annual meeting in Chicago, Jan. 20-24, 1945. The courses will deal with the shoulder, the hip, the knee and the foot. The instruction periods will deal first with the orthopedic anatomy, then with the practical application from the standpoint of symptoms and pathology, the treatment of disease conditions occurring in each one of these regions and finally the treatment of traumatic conditions. Four courses on physiology will be offered covering nerves, joints, bones and muscles as they pertain to various phases of orthopedic surgery. There will also be courses on infantile paralysis, spastic paralysis, fractures and x-rays in orthopedic surgery. On Saturday evening, January 20, the instructional course dinner will be held with an "information please" type of program of interest to military and civilian orthopedic surgeons. During the session a symposium on degenerative hip pathology is also planned as well as a series of talks on fractures, reconstruction surgery, treatment of infections and trauma.

Cancer Society Absorbs Foundation.—The recently formed National Foundation for the Care of Advanced Cancer Patients was absorbed October 10 into the American Cancer Society, according to the *New York Herald Tribune*. Under the arrangement, it was stated, the cancer society, which is 31 years old, will devote part of the funds collected nationally to provide care for incurable cancer patients of moderate means in addition to its present activities in supporting research and education in the prevention and cure of cancer. The merger was announced by Clarence C. Little, ScD., managing director of the American Cancer Society, and Julius J. Perlmuter, organizer and president of the national foundation, which was incorporated last May (*THE JOURNAL*, May 20, p. 221). It was stated that the organizations joined forces to avoid any confusion that might follow separate national campaigns for funds. The foundation will temporarily maintain its offices at 1450 Broadway, but its activities and records were to be transferred immediately to the cancer society's offices at 350 Madison Avenue. In an announcement Dr. Frank E. Adair, president of the American Cancer Society and vice president of the foundation, said that the former group will stimulate establishment of hospitals and homes to care for hopeless cancer patients and contribute funds for their support. Heretofore this organization has emphasized educational campaigns in the prevention and early detection of cancer, contributing to the support of cancer research and clinics throughout the country.

Oct. 4, 1944.

Compulsory Social Insurance from the Cradle to the Grave

As pointed out previously in *THE JOURNAL*, the scheme of the government for a national health service, which has produced the greatest crisis ever faced by the medical profession, is only one phase of the socialistic trend of British politics. The climax—for the present, at any rate—of this trend is the social insurance plan which has just been published. This is the Beveridge scheme, which has been described in *THE JOURNAL*, with some modifications. It extends compulsory social insurance to the entire population and so includes the millionaire as well as the humblest manual worker. Incidentally, this renders unlikely any favorable action on the demand from the profession that the upper 10 per cent of the population who do not require a national health service should not be included in it. The scheme will cost \$3,250,000,000 in the first year, increasing to \$4,155,000,000 in 1975. This will be provided by contributions from workers, employers, taxpayers and ratepayers. A Ministry of Social Insurance is to be set up as soon as possible. The main benefits will be as follows:

Sickness: Single man or woman or man with wife earning, \$5 a week; man with wife not earning, \$8; married woman earning, \$3; dependent's allowance, \$3.

Invalidity: Single man or woman or man with wife earning, \$4; man with wife not earning, \$7; married woman earning, \$3; dependent's allowance, \$3.

Unemployment: Single man or woman or man with wife earning, \$5; man with wife not earning, \$8; married woman earning, \$4; dependent's allowance, \$3.

Retirement Pension: Single man or woman or man with wife earning, \$4; man with wife not earning, \$7; married woman earning, \$4.

Family Allowances: \$1 a week for each child except the first; more school meals and milk.

Provision is also made for maternity, death, widows and orphans and industrial training.

At present twenty million employed persons are covered by insurance. The new plan, which extends insurance to everybody, will bring in another twenty-seven million. Each insured person will pay in the form of a stamp a single weekly contribution for all the benefits to which he is entitled. For employed men over 18 the total contribution will be \$1.50 weekly, of which nearly half will be paid by the employer. This figure includes 12 cents a week which men now pay under a separate industrial injury insurance scheme. The unemployment benefit will be payable for not more than thirty weeks continuously. For employed women the weekly contribution is \$1 a week, of which the employer pays more than half.

The government states that its first duty is to protect the country against aggression and the next is to secure the general prosperity and happiness of its citizens. Growth of the national power to produce, with accompanying opportunities for increased well-being, leisure and recreation, must be fostered, it is declared. Plans for the prevention of individual poverty resulting from those hazards of personal fortune over which individuals have little or no control must also be made by the government, it is held. Hence the need for social insurance. The stability of so vast a scheme depends on

strict administrative economy in every sense. This is not a matter for the government alone but requires the full cooperation of the public.

FAMILY ALLOWANCES

The proposals for family allowances are based on two principles: that nothing should be done to remove from parents the responsibility of maintaining their children and that it is in the national interest to help parents in discharging that responsibility. The scheme is not intended to provide full maintenance for each child but rather a general contribution to the needs of families with children. The purpose can be best fulfilled by giving a substantial part of the benefit in kind. The present school meals and milk will therefore be extended. It is estimated that this will increase the cost to \$300,000,000 a year—a figure which does not fall far short of the total cash allowances to parents. The first child is excluded from the flat rate allowance of \$1 a week because it is assumed that one child can be maintained from family earnings.

SICKNESS BENEFIT

Sickness benefit will be payable for the first three years of any continuous period of sickness. After that the lower rate of invalidity benefit will be paid. The government feels that sickness benefits of unlimited duration would be psychologically unwise and would tend to encourage persons subject to recurrent periods of sickness to lapse into chronic invalidity.

RETIREMENT PENSIONS

The prevention of want in old age is a policy on which the government sets great store. Government actuaries have estimated that in the twenty years from 1945 to 1965 the population of pensioners over working age will grow from 3,400,000 to 5,300,000, whereas the number of contributors will be practically stationary at about 21,000,000. In the ten years from 1965 to 1975 there will be a further increase of about 800,000 in the pensioners, while the contributor population will fall by over 1,000,000. These figures are based on the prewar birth and death rates. It may become a matter of vital importance to keep up the national income by encouraging the continuance of productive work by those who have reached the pensionable age. The government therefore proposes that for any one who works beyond the pensionable age and claims his pension later, the benefit rate will be increased by \$0.25 weekly for each extra year of work.

CONCLUSION

The government has expressed gratitude to Sir William Beveridge for his great work in preparing his comprehensive and imaginative report. The main tribute is the embodiment of so much of his plan in the proposals, which are believed to afford an adequate basis of social insurance for many years to come. They round off a notable chapter in the history of British social insurance, which since its beginning thirty-three years ago in the National Insurance Act has grown steadily in scope. The present scheme makes provision against every one of the main attacks which economic ill fortune can launch against individual well-being and peace of mind proponents of the plan maintain. They do not explain why the government worked out in detail this revolutionary plan of national compulsory insurance for all persons and for all purposes, from the cradle to the grave, during the greatest of all wars, which for a time placed the very existence of this country in danger. Some explanations are suggested, however. During the war all our activities have been severely controlled, so as to subordinate everything to victory. One result was the abolition of unemployment. So the argument arose "If the government can prevent unemployment in time of war, it can do so in time of peace." After the war of

1914-1918 the country was left to its own devices and there was a period of severe unemployment. The government has now assumed responsibility for dealing with unemployment by prevention or subsidy. In the second place, family allowances are designed to help parents in their responsibility and so encourage parenthood in the face of threatened decline of population.

Home Leave of Soldiers for Parenthood Resented

Much discontent has been caused among men of long service in the Middle East by what they regard as a gross interference with a man's most intimate private affairs. This arises out of publication of an order that married men with more than three years of service in the Middle East could obtain compassionate leave on the grounds that they wanted to return home "to start a family." Within a few days there were more than 1,000 applications. Three weeks later there was an amendment to the original order, which restricted posting to men whose wives were over 35 and who could show good reason why they had not started a family before the war. Wives and husbands were required to produce a medical certificate that they were willing and able to have children. Since this amendment, which makes it difficult for more than a handful of men to obtain posting, in spite of the fact that hundreds had already joyfully written home about the new facility, chaplains and welfare officers have found the men unhappy. What their wives in Britain will think is not difficult to imagine. Most of the soldiers, even the married ones, are willing to serve abroad for three years if necessary, owing to war conditions, but after that they want to go home. Nothing could be worse than the disappointment after hopes were raised by the original order.

BUENOS AIRES

(From Our Regular Correspondent)

Sept. 22, 1944.

Social Care of Patients with Heart Disease

The Department of Social Care to Cardiac Patients in Buenos Aires, of which Dr. Rafael A. Bullrick is the head, has a central department of social assistance and nine dispensaries in the Ramos Mejia, Rawson, Alvear, Pirovano, Durand, Salaberry, Alvares and Tornú hospitals. All the centers are well provided with the necessary means for preventing heart disease and for giving therapy to patients. The work carried on by the department during the last four and a half years is of great importance. The department is supported by the government, but donations are also given by the public. The department gives medical care to ambulatory patients, hospitalization for as long as it is necessary, medical care and guidance to pregnant and nursing mothers with heart disease and to children with heart disease and help in securing proper positions for young people with heart disease. Patients with heart disease who are unable to work and have no family to support them are admitted to institutions in which they will be given the necessary care.

National Department of Public Health

The National Department of Public Health and Social Assistance of Argentina was created Oct. 21, 1943 to supplant the National Department of Public Hygiene. Recently the government changed the functions of the department. From now on all work concerned with public beneficence and social care will be carried on in the Department of Social Assistance, which is a branch of the Secretariat of Work and Public Aid. The functions of the National Department of Public Health are concerned with the prevention and control of diseases. Dr. Eugenio A. Galli, head of the National Department of Public Health, has resigned; Dr. Manuel Augusto Viera has been appointed to the position.

Prevention of Typhoid

Vaccination against typhoid for all persons living in areas in which typhoid is frequent, including children over 3 years of age, became obligatory by a decree of the government which was recently published. A certificate will be given to all persons after vaccination. It should be shown by parents to teachers and by workers to employers. Managers and consulting physicians of working centers will be in charge of demanding the certificate as a requirement for admission to work. Persons who have suffered from typhoid in the recent past and those in poor health can refuse vaccination if they present a medical certificate to the vaccination department. The vaccination and proper medical after-care are given free of charge. The vaccine to be used is that prepared by the National Department of Public Health or any of the vaccines authorized by the National Department of Public Health. Private clientele will pay for vaccination at home. The period of time after which revaccination, either partial or total, is to be administered will be reported later. Infractions of the law will be punished by fines, which will be used to help defray the expenses of the antityphoid campaign. The incidence of typhoid in the Argentine army is negligible because the soldiers are given the vaccines when entering the army. Several cases of typhoid were reported from San Juan shortly after occurrence there of an earthquake in January 1944. Administration of vaccines soon after the cases were reported prevented further spread. The vaccine prepared by the Bacteriologic Institute of Buenos Aires is administered in three progressive doses.

Distribution of Penicillin in Argentina

Penicillin is not available to Argentine physicians; they have to order it from other countries. Penicillin is not produced in this country, although certain scientific institutions and pharmaceutical firms are carrying out laboratory and scientific studies on penicillin. Large amounts of it are to be sent in the near future from the United States to Argentina. No import duty will be charged. The National Department of Public Health appointed a committee in charge of the importation of the drug to Argentina, national distribution of the substance and supervision of prices. The committee sent formularies to physicians for obtaining the amounts of the drug which they may need for their patients.

Marriages

NORMAND EDMOND DUROCHER, Ecorse, Mich., to Miss Audrey Mae Brady of Gulfport, Miss., at Charlotte, N. C., September 3.

MARION AUGUSTUS BALDWIN, Fort Gaines, Ga., to Miss Elizabeth Frances Baldwin of Montgomery, Ala., in September.

GEOFFREY HERMAN BINNEVELD, Leesburg, Fla., to Miss Ellen May Whitt of Yalaha in Charlottesville, Va., September 15.

WILLIAM F. X. CAMPION, Brooklyn, to Miss Margarita Anita Corrigan of Bay Ridge, N. Y., September 16.

CHARLES ALOYSIUS ROGERS, Upper Montclair, N. J., to Miss Mary P. Robertshaw of Montclair, September 30.

JOHN G. CHESNEY to Miss Audrey Hasler, both of New York, in Montgomery, Ala., September 15.

BROOKE ROBERTS, Bala-Cynwyd, Pa., to Miss Anna W. Ingersoll in Whitmarsh, September 16.

WILLIAM SHERARD CHAPMAN to Miss Lois Elizabeth Smith, both of Florence, S. C., September 16.

JAMES R. FLAHERTY to Miss Kathryn M. Gully, both of Worcester, Mass., August 26.

CHARLES A. DE WERT to Miss Elizabeth L. Duman, both of Cincinnati, September 14.

RICHARD V. DAUT to Miss Jean Wilkens, both of Muscatine, Iowa, September 28.

CLIFFORD T. SMITH to Mrs. Loine Arthur, both of Houston, August 23.

Deaths

James Addison Babbitt * Haverford, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1898; emeritus professor of clinical otolaryngology at his alma mater and associate professor of otolaryngology at the Medico-Chirurgical College, Graduate School of Medicine, University of Pennsylvania; served as professor of hygiene and physical education at Haverford College, becoming emeritus in 1928; member of the United States Football Rules Committee from 1906 to 1925; a fellow and one time president and secretary of the American Laryngological Association; fellow and past president of the American Academy of Ophthalmology and Otolaryngology and the American Laryngological, Rhinological and Otolological Society; fellow of the American Otolological Society, Inc., and the Philadelphia Laryngological Association; fellow and past chairman, executive committee, section on otolaryngology, College of Physicians of Philadelphia; fellow and member of the board of governors of the American College of Surgeons; during World War I served in France and Germany, working with the hospital service of the American Red Cross with the rank of major; specialist certified by the American Board of Otolaryngology; member of the courtesy staffs of the Bryn Mawr Hospital, Bryn Mawr, Presbyterian, Chestnut Hill and Methodist hospitals, Philadelphia; consulting otolaryngologist to the Mercy-Fitzgerald Hospital, Darby, Pa., Children's Hospital of the Mary J. Drexel Home, Children's Hospital, and Misericordia Hospital, Philadelphia; consulting otolaryngologist and acting chief, department of otolaryngology at the Lankenau Hospital, Philadelphia, where he died October 15, aged 74, of cerebral hemorrhage.

Edward Leonard Kickham * Boston; Tufts College Medical School, Boston, 1923; specialist certified by the American Board of Obstetrics and Gynecology, Inc.; member of the New England Obstetrical and Gynecological Society and the Boston Obstetric Society; treasurer of St. Luke's Guild of Physicians; fellow of the American College of Surgeons; since 1930 instructor in gynecology at his alma mater; special lecturer at the Boston College School of Social Work; formerly surgeon of the fire department; served during World War I; senior obstetrician and gynecologist at Carney and St. Elizabeth's hospitals; gynecologist at the New England Medical Center; died in the Cardinal O'Connell House of St. Elizabeth's Hospital August 10, aged 49, of ulcerated colitis.

Denis Lane McAuliffe * North Vernon, Ind.; Miami Medical College, Cincinnati, 1902; formerly instructor in anatomy and lecturer in medicine and materia medica at his alma mater; for thirty years secretary-treasurer and once president of the Jennings County Medical Society; for many years secretary of the Fourth District Medical Society; once president and for fifteen years secretary of the Tri-County Medical Society; member of the Southern Medical Association and the Mississippi Valley Medical Association; at one time county health officer; on the staff of the Schneck Hospital, Seymour, where he died September 18, aged 79, of myocardosis and bronchopneumonia.

Victor Lupu Schragar * Chicago; Universitatea din Bucuresti Facultatea de Medicina, Rumania, 1901; Dearborn Medical College, Chicago, 1904; Rush Medical College, Chicago, 1907; associate professor of surgery at Northwestern University Medical School; professor of surgery at the Cook County Graduate School; formerly assistant professor of surgery at Rush Medical College; a founder member of the American Board of Surgery; a member of the Chicago Surgical Society; fellow of the American College of Surgeons; on the staffs of Mount Sinai, Garfield Park Community, Walther Memorial, Loretto and Cook County hospitals; died October 15, aged 66, of hypertension and heart disease.

Hiram La Mont Youtz, Webster City, Iowa; Johns Hopkins University School of Medicine, Baltimore, 1905; member of the Iowa State Medical Society; during World War I served overseas as a captain in the medical corps of the U. S. Army in command of Field Hospital number 40; honorably discharged in 1919; in 1935 assigned to active status as captain, medical reserve, Civilian Conservation Corps, in Iowa; served as college physician at the South Dakota State College, Brookings, for four years; died September 27, aged 69, of carcinoma of the sigmoid with metastasis to the liver.

Bertis Charles Gwaltney, Fort Branch, Ind.; Indiana University School of Medicine, Indianapolis, 1930; member of the Indiana State Medical Association; health officer of Gibson

County; in 1943 appointed assistant collaborating epidemiologist of Indiana; for thirteen years a teacher in various schools in Gibson County, including a year at Wolfe Lake in Northern Indiana, serving as principal at the Mackey High School; a director of the Lynnville National Bank; on the staff of the Gibson General Hospital, Princeton; died August 9, aged 50, of coronary thrombosis.

Arthur E. Bonesteel, Los Angeles; University of Denver Medical Department, 1894; member of the Colorado State Medical Society; formerly on the staff of St. Luke's Hospital in Denver; died July 31, aged 73, of cardiovascular disease.

Samuel Pierson Brush, Babylon, N. Y.; Albany Medical College, 1908; fellow of the American College of Surgeons; died July 5, aged 61, of arteriosclerosis.

Willard James Burns, Washington, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1897; member of the Medical Society of the State of Pennsylvania; died June 28, aged 77, of coronary thrombosis and acute gastritis.

George H. P. Christman, East Washington, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1881; member of the Medical Society of the State of Pennsylvania; served during World War I; died June 24, aged 85, of acute dilatation of the heart, arteriosclerosis and coronary disease.

Leo V. James Conlin, St. Paul; University of Minnesota Medical School, Minneapolis, 1931; health officer of North St. Paul and deputy coroner of Ramsey County; on the staffs of St. John's and St. Joseph's hospitals; died June 10, aged 43, of coronary occlusion.

Edward C. Gager, St. Paul; University of Minnesota College of Medicine and Surgery, Minneapolis, 1905; member of the Minnesota State Medical Association and the Minnesota Dermatological Society; fellow of the American College of Physicians; clinical instructor in dermatology at his alma mater; chief, venereal disease clinic, Wilder Dispensary; attending dermatologist, Ancker Hospital; died in the Bethesda Hospital July 29, aged 61, of acute myocardial failure following an operation for intestinal obstruction due to gallstones in the ileum.

Henry J. Goodwyn, Carrollton, Ga.; Atlanta College of Physicians and Surgeons, 1902; member of the Medical Association of Georgia; president of the Carrollton Federal Savings and Loan Association; died June 24, aged 70, of carcinoma of the liver.

Charles M. Hanby, Wilmington, Del.; Southern Homeopathic Medical College, Baltimore, 1902; member of the Medical Society of Delaware; a member and for many years president of the city board of health; on the staffs of the Memorial, Delaware and Wilmington General hospitals; served as a member of the board of directors of the Alfred I. du Pont Institute of the Nemours Foundation; died July 27, aged 69, of coronary occlusion.

James I. Hembree, Atlanta, Ga.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1912; died in the Crawford W. Long Memorial Hospital July 5, aged 54, of coronary thrombosis.

G. W. Holmsley, Comanche, Texas (licensed by years of practice); died July 8, aged 73.

William Brayton Holt * Oak Ridge, Tenn.; University of Minnesota Medical School, Minneapolis, 1924; member of the Minnesota State Medical Association; formerly on the staff of St. Barnabas Hospital, Minneapolis; died July 26, aged 46, of congestive heart disease, coronary sclerosis and hypertension.

Ernest Walker Irving, Memphis, Tenn.; Meharry Medical College, Nashville, 1897; formerly inspector in city schools for the board of health; died July 18, aged 74, of angina pectoris.

Addison Le Clare Judd, Kanawha, Iowa; Keokuk Medical College, College of Physicians and Surgeons, Keokuk, Iowa, 1902; member of the Iowa State Medical Society; served on the staff of the Lutheran Hospital, Hampton; died July 27, aged 79, of senility.

Christopher C. Kesner, LeRoy, Kan.; Louisville Medical College, Louisville, Ky., 1884; served as local surgeon for the Missouri Pacific Railroad; died June 15, aged 87, of cerebral hemorrhage.

Lucas Allen Miller * Colorado Springs, Colo.; the Hahnemann Medical College and Hospital, Chicago, 1898; first lieutenant in the medical reserve corps of the U. S. Army, not on active duty; died August 21, aged 76, of coronary thrombosis.

James Franklin Owens, Springfield, Mo.; Northwestern Medical College, St. Joseph, 1892; member of the Missouri State Medical Association; formerly lecturer at the Ensworth

Central Medical College; while a resident at St. Joseph, served as president of the board of public health, city health physician and county physician; died August 1, aged 74, of cerebral and gastric hemorrhages.

Edwin N. Reinert * Cleveland, Wis.; Milwaukee Medical College, 1902; died in the Memorial Hospital, Sheboygan, August 1, aged 67, of uremia and carcinoma of the prostate with metastasis.

William T. Rickman, Sapulpa, Okla.; University of West Tennessee College of Medicine and Surgery, Memphis, 1916; died in the Moton Memorial Hospital, Tulsa, June 17, aged 65, of cardiovascular disease.

Frederick Charles Roberts, Easton, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1898; member of the Medical Society of the State of Pennsylvania; past president of the Northampton County Medical Society; at one time mayor of Easton; emeritus chief of the medical staff of Easton Hospital; died suddenly October 13, aged 74, of cardiac infarct.

Joseph Horace Shull, Stroudsburg, Pa.; Bellevue Hospital Medical College, New York, 1873; also a lawyer; state senator from 1886 to 1890; in 1904 elected to Congress as a representative for a term; served as president of the Monroe County Medical Society and the Monroe County Bar Association, on

John Sanders Taylor, Mount Pleasant, Texas (licensed in Texas under the Act of 1907); served as health officer of Mount Pleasant for many years; died June 19, aged 83, of heart disease.

Thomas L. Underwood, Sebastopol, Miss.; Memphis (Tenn.) Hospital Medical College, 1889; died July 27, aged 84, of mitral regurgitation.

Lee Wilbert Wiggins, Doraville, Ga.; Atlanta School of Medicine, 1908, member of the Medical Association of Georgia; served during World War I; on the staff of the Crawford N. Long Memorial Hospital, Atlanta; died in the Veterans Administration, Atlanta, July 20, aged 67, of hypertension and coronary arteriosclerosis, cerebral thrombosis with hemiplegia.

Maurice Houston Wilkinson, Los Angeles; the Hahnemann Medical College and Hospital, Chicago, 1915; formerly professor of internal medicine at the Illinois Post-Graduate Medical School, Chicago; served during World War I; captain, medical corps, Army of the United States, not on active duty, served on the staffs of various Veterans Administration facilities, died August 25, aged 55, of coronary occlusion.

David York Willbern, Runge, Texas; Medical Department of Tulane University of Louisiana, New Orleans, 1900; served on the school board for many years; died July 13, aged 73, of lobar pneumonia following a cerebral hemorrhage.

LIEUT. FRANCIS J. BROCCOIO
(MC), U.S.N.R., 1917-1943

LIEUT. (JG) HENRY B. LANDAAL
(MC), U.S.N.R., 1918-1944

CAPT. EUGENE FRANCIS HAVERLY
M. R. C., U. S. A., 1912-1944

the staff of the General Hospital of Monroe County, East Stroudsburg; died August 8, aged 95, of uremia.

Marvin R. Smith, Cordele, Ga.; University of Georgia Medical Department, Augusta, 1905; member of the Medical Association of Georgia; died July 12, aged 65, of acute dilatation of the heart.

W. Charles Willis, Allentown, Pa.; Eclectic Medical College of the City of New York, 1907; died July 2, aged 67.

Harry M. Wilson, Evans City, Pa.; University of Maryland School of Medicine, Baltimore, 1889; member of the Medical Society of the State of Pennsylvania; vice president of the Citizens National Bank; died July 25, aged 78.

KILLED IN ACTION

Francis Joseph Broccoio, Cicero, Ill.; Loyola University School of Medicine, Chicago, 1941; served an internship at the Cook County Hospital, Chicago, where he had been a resident in otology, laryngology and rhinology; commissioned a lieutenant (jg) in the medical corps of the U. S. Naval Reserve on Jan. 26, 1942, promoted to lieutenant Oct. 1, 1942; had been awarded the Silver Star; killed in action while at sea in the South Pacific area; aged 26; presumptive date of death, Oct. 13, 1943, according to the Navy Department.

Henry Byron Landaal, Waupun, Wis.; Medical College of Virginia, Richmond, 1943; served an internship at the State of Wisconsin General Hospital, Madison, commissioned a lieutenant (jg) in the medical corps, U. S.

Naval Reserve on April 6, 1943, killed in action off the coast of France June 9, aged 26.

Eugene Francis Haverly, Pittsburgh; Georgetown University School of Medicine, Washington, D. C., 1938; served an internship at the Mercy Hospital; formerly resident physician at the Children's Hospital, Cincinnati, and the Cincinnati General Hospital; commissioned a first lieutenant in the medical reserve corps of the U. S. Army on June 18, 1938; began extended active duty on July 7, 1941 and assigned to the Station Hospital at Indiantown Gap, Pa.; later promoted to captain; had been stationed in England, Tunisia and Salerno, awarded the Legion of Merit and Silver Star for meritorious service at Anzio beach head, killed in action in Italy, February 29, aged 31.

Bureau of Investigation

MISBRANDED PRODUCTS

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the Federal Security Agency

[EDITORIAL NOTE.—These Notices of Judgment are issued under the Food, Drug and Cosmetic Act, and in cases in which they refer to drugs and devices they are designated D.D.N.J. and foods, F.N.J. The abstracts that follow are given in the briefest possible form: (1) the name of the product; (2) the name of the manufacturer, shipper or consigner; (3) the date of shipment; (4) the composition; (5) the type of nostrum; (6) the reason for the charge of misbranding, and (7) the date of issuance of the Notice of Judgment.]

Hillys "H-R 5."—Morris William Hillinger, trading as Hilly Medicinal Products, Pasadena, Calif. Shipped Oct. 7, 1940. Composition: essentially small amounts of an ephedrine salt, caffeine, sodium phosphate, reducing sugars and water, with caramel coloring. Misbranded because despite the 0.31 grain of ephedrine hydrochloride present in each fluid ounce, the label failed to warn that frequent or continued use might cause nervousness, restlessness or sleeplessness, and that persons suffering from high blood pressure, heart disease or thyroid trouble should not use such drug except on competent advice. Further misbranded because of false and misleading statements in labeling, which represented that the product would be efficacious for use after overindulgence in alcohol, and in the cure, mitigation, treatment or prevention of alcoholism.—[D.D.N.J., F.D.C. 808; December 1943.]

Howell's Antiseptic Healing Oil.—Howell Company, Inc., New Orleans. Shipped between Feb. 21, 1940, and Jan. 6, 1941. Composition: essentially an oil containing camphor and 2.4 per cent of phenol. Adulterated because not possessing the phenol strength claimed and not antiseptic as represented by the name. Misbranded because label failed to warn that a bandage should not be used when product was applied to fingers and toes, and that it should be used according to directions and in no case on large areas of the body. Further misbranded because label statement "2% carbolic acid" and claim "Antiseptic" were false and misleading. Also misbranded because of claims on carton that preparation would relieve pain and soreness in carbuncles, erysipelas, boils and iteh, and be efficacious for ulcers, old sores and skin eruptions.—[D.D.N.J., F.D.C. 807; December 1943.]

Meltozone Tablets.—Standard Drug Company, Inc., Spartanburg, S. C. Shipped Feb. 28 and March 13, 1941. Composition: essentially small amounts of extracts of plant drugs, including nux vomica, and a phosphide of some metal such as zinc. Misbranded because label did not warn against chronic phosphorus poisoning, which might follow the frequent or continued use of a product containing zinc phosphide, or against cantharides, the use of which might cause nausea, vomiting and abdominal pains, and seriously injure the kidneys, hence rendering it hazardous for use by persons afflicted with kidney disease; further misbranded because of false label representations regarding its alleged efficacy in the cure, mitigation, treatment or prevention of sexual debility.—[D.D.N.J., F.D.C. 805; December 1943.]

Nomo for Piles, Sanafrío and Asmolac.—Albert B. Hirschman, trading as Hirschman Laboratories and Sanafrío Laboratories, San Pedro, Calif. Shipped between May 14 and July 1, 1940. Composition: Nomo for Piles, essentially benzocaine, boric acid, eucalyptus oil, fixed oils, and zinc oxide; Sanafrío, essentially fat, zinc oxide, camphor and menthol; Asmolac, chiefly water, alcohol, plant extractives, alkaloids, reducing sugars and the iodides of potassium and sodium. Nomo for Piles misbranded because labeling falsely represented product as a competent treatment for all cases of hemorrhoids and as efficacious in relieving soreness and pain in that condition; further misbranded because labeling was misleading in not revealing that the preparation was not a treatment for all cases of hemorrhoids and that competent advice should be obtained in cases of excessive bleeding. Sanafrío misbranded because label falsely represented it as effective in treating chest colds and sore throat. Asmolac misbranded because directions for use mentioned no limitation as to duration of use, and because, though it contained iodine or iodides and the alkaloids of belladonna and hyoscyamus, the labels failed to warn that the product should be used with caution in the presence of certain conditions; further misbranded because directions falsely represented that, when used as directed in asthmatic spasms, it often would completely prevent these; also misbranded because labels did not declare the name and quantity or proportion of alkaloids of belladonna and hyoscyamus present.—[D.D.N.J., F.D.C. 757; September 1943.]

Re-Duce-Oids Capsules.—American Medicinal Products, Inc., Los Angeles. Shipped between April 7 and June 9, 1941. Composition: essentially a mixture of thyroid and potassium iodide (0.5 grain and 0.92 grain, respectively, per capsule), phenolphthalein and milk sugar. Misbranded because of false label representation that the mixture was an adequate and appropriate treatment for obesity.—[D.D.N.J., F.D.C. 783; September 1943.]

Sani+Cross Adhesive Strips and Tip Top Emergency First Aid Kits.—Gero Products, Inc., South Boston, Mass. Shipped Jan. 27 and April 28, 1942. The strips were adulterated because purity and quality fell below that which they purported to possess as being supposedly suit-

able for use on cuts and other wounds. Misbranded because falsely represented to be thus suitable. The Kits were adulterated because the absorbent cotton that they contained was not sterile but was contaminated with living bacteria, and hence fell below the standard of the United States Pharmacopeia. Misbranded because claims "First Aid Kit . . . For small cuts . . . Be Prepared for Emergencies" were false and misleading when applied to kits containing items which were not sterile. Further misbranded in that labels did not accurately declare quantity of contents, and containers were so made and filled as to be misleading.—[D.D.N.J., F.D.C. 795; September 1943.] Another consignment of Sani + Cross Adhesive Strips shipped by World Merchandise Exchange, New York, Oct. 9, 1941, was declared adulterated and misbranded for essentially the same reasons as those named above and reported under a separate Notice of Judgment 797.

Wise's Kollasol Tablets.—Wise's K. C. Homeopathic Pharmacy, Kansas City, Mo. Shipped Jan. 22, 1942. Composition: essentially oxyquinoline sulfate, potassium sulfate and lactose. Misbranded because labeling falsely represented that product would eliminate bacteria, guard against toxins and ptomaines, promote healing, provide healthy granulation with a minimum of scar tissue, control hemorrhage, prevent diphtheria and other infections, external and internal, and provide adequate medication in dentistry for toothache, pyorrhea, trench mouth, gingivitis and ulcerations, as well as diseases of the eye, ear, nose and throat, the genitourinary tract and skin conditions including varicose ulcers, carbuncles, erysipelas, athlete's foot and some other things.—[D.D.N.J., F.D.C. 789; September 1943.]

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Medical Practice Acts: Right of Drugless Practitioner to Perform Hemoglobin Test.—The Board of Medical Examiners of California issued a "Drugless Practitioner's certificate of license" to King authorizing him to practice as a drugless practitioner. Subsequently an accusation was filed with the board, charging that King was guilty of unprofessional conduct in that on a stated day he penetrated the tissues of a stated patient in the treatment of a certain physical condition, that he had on stated occasions prescribed or administered drugs and that he had unlawfully used the title "doctor" or the prefix "Dr." After hearing, the board found the charges sustained and revoked King's license to practice. King then brought mandamus proceedings to review the order of revocation. The trial court found that the evidence warranted a finding of guilt only with respect to the unprofessional conduct in the charge that King had unlawfully used the title "doctor." This violation, the trial court held, however, was so trivial as to be insufficient to support the order of revocation entered by the board, and the trial court accordingly ordered that King's license should be suspended for six months only. King then appealed to the district court of appeal, first district, division 2, California.

The first count of the accusation filed with the board charged King with unprofessional conduct in that he did on a date specified "penetrate the tissues of" a stated patient "in the treatment of a certain disease, injury, deformity and other physical and mental conditions" in violation of the laws of the state relating to the practice of the healing arts. The evidence to support that charge was to the effect that King made a hemoglobin test of the blood of the person named, at a lecture that he was giving, by taking a drop of blood from the earlobe of that person, using what was vaguely described as "a long instrument similar to a pencil." He then compared the drop of blood so taken with a hemoglobin chart and told the person what the reading showed. No charge was made for the test. The question is thus presented, said the appellate court, as to whether or not the action of King constituted a penetration of the tissues within the intentment of that section of the Business and Professional Code which states that the penetration of the tissues of any human being by the holder of a drugless practitioner's certificate in the treatment of any physical or mental condition constitutes unprofessional conduct. In the opinion of the court, King's action in this respect constituted diagnosis, a procedure he was lawfully permitted to perform in view of the fact that among the educational requirements imposed on an applicant for a license to practice as a drugless practitioner is a requirement that he shall have taken at least a five hundred hour course in diagnosis in his so-called professional school and

in view of the fact that "even in the case of drugless practitioners," as said by the Supreme Court of California in *People v Jordan*, 172 Calif 391, 156 P 451, "Intelgent treatment may only follow correct diagnosis." The court also alluded to the fact that among the questions propounded in the examinations given applicants for licenses to practice as drugless practitioners are questions calling for the description of the Dick test and the Schick test. The court finally pointed out that the section prohibiting drugless practitioners to penetrate the tissues merely prohibits the penetration of the tissues "in the treatment of a disease or other physical or mental condition" and that there was no evidence presented that King's action came within the language of this section. The court was of the opinion that King's action in taking the hemoglobin test did not come within the letter or spirit of the law.

The second count of the accusation filed with the board charged unprofessional conduct on the part of King in that he did "prescribe, use or administer drugs or what are known as medicinal preparations, to wit 'Gland capsules 'Min-a-rex' and 'Vitamin' capsules . . . in the treatment of a disease, deformity or other physical condition." The members of the board were unanimous in voting that with respect to this count King was guilty as charged. This was done, said the appellate court, notwithstanding the fact that no evidence was offered relative to the use or prescription of any 'gland capsules' and that the undisputed evidence showed that the other compounds were *not* used "in the treatment of a disease, deformity or other physical condition." In the proceeding before the board to show that these compounds were "drugs or what are known as medicinal preparations," a state chemist testified before the board as to his chemical analysis of the contents of the mixture and concluded with the statement that "Min-a-rex" was 'probably sea water or something of a similar composition.' The undisputed evidence was that the 'Vitamin Capsules' were food substitutes containing "wheat germ oil" and were sold by King in the original sealed package under the trademark of the manufacturer without other representation than what was printed on the label. No evidence was introduced to prove that they were prescribed or used for the purposes denounced in the code, namely, "in the treatment of any physical or mental condition of the human being." Further, as indicative that there was a complete failure of proof of the charges made in this count, the court noted that the board denied King the right to present evidence of two essential elements of his defense, namely, that no drugs or medicines were used in the treatment of any disease or physical condition and that the packages sold met the requirements of the pure food laws of the United States and of the state. If King had been permitted to make this proof, the court concluded, no reasonable person could have found him guilty of a charge of using drug or medicinal preparations in the treatment of any physical or mental condition and the denial of that right was arbitrary, unreasonable and a breach of discretion on the part of the board.

The third count of the accusation filed with the board charged King with violating section 2409 of the Business and Professions Code, which reads as follows:

Unless a person licensed and authorized under this chapter or any preceding medical practice act to use the title 'doctor' or the letters or prefix 'Dr.' holds a physician's and surgeon's certificate, the use of this title or these letters or prefix without further indicating the type of certificate he holds, constitutes unprofessional conduct within the meaning of this chapter.

The accusation, said the court, does not allege that King was "licensed" under any act "to use the title 'doctor' or the letters or prefix 'Dr.'" The license was not offered in evidence. The accusation filed with the board alleged and the answer admitted that King was issued a "Drugless Practitioner's certificate of license" authorizing him to practice as a drugless practitioner. It does not appear either in the statute or in the record that such license authorized King to use the title "doctor" in any form. The purpose of the statute is clear. If a person is licensed under any medical practice act to use the word "doctor" in relation to a profession other than that of physician or surgeon, he must indicate the type of certificate he holds. The court was unable to find any provision in the law or of any "preceding medical practice act" which authorizes any agency

to license a drugless practitioner to use the word "doctor" or the prefix "Dr" and, unless such a license has been issued the court held the section does not apply. It seems apparent, said the court, that the purpose of the section was to prevent misrepresentations and fraud and that there was no intent to appropriate these titles to the exclusive use of those who held the certificate of a physician or surgeon. Thus we have doctors of medicine, doctors of philosophy and many other types of "doctors" who are not licensed under any medical practice act and therefore not included in this section.

The court accordingly held that the revocation of King's license was not warranted. The court further held that the trial court had erred when it ordered the suspension of King's license. By the terms of the Business and Professions Code, said the court, all disciplinary action with respect to physicians and surgeons and drugless practitioners is lodged with the board of medical examiners, and a court reviewing the orders of the board is without power to substitute its discretion for that of the board in the matter of the form of discipline to be imposed. The appellate court in effect reversed the order of the board of medical examiners revoking King's license to practice—*King v Board of Medical Examiners*, 151 P (2d) 282 (Calif, 1944).

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1934 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Journal of Physiology, Baltimore 141:613-750 (July) 1944

- Factors Responsible for Intestinal Phase of Gastric Secretion W. D. Beamer, M. H. F. Friedman, J. E. Thomas and M. E. Rehfuess. —p 613
- Some Factors Affecting Resistance of Ejaculated and Epididymal Spermatozoa of Boar to Different Environmental Conditions. J. F. Lasley and R. Bogart —p 619

Determination of Placental Site in Bleeding During Pregnancy.—McCort and his associates review roentgenologic studies on 132 patients with the presenting symptom of bleeding during the last trimester of pregnancy. The accuracy of this method of examination was 87.8 per cent, with best results in the group diagnosed as negative for placenta previa (97 per cent). The roentgen examination for placenta previa has proved to be a valuable adjunct to the sterile pelvic examination. The two examinations are somewhat complementary. The former enables the obstetrician to treat bleeding cases with greater exactitude. A soft tissue roentgenographic study of the abdomen is first made. If, after careful study, the main portion of

the placenta is found to lie in the fundus, it is reported as negative for placenta previa and no further examination is made. If the placenta is not visualized in this position, an air cystogram is done to determine if there is any tissue intervening between the fetal head and the bladder wall. The following signs are of value in positive diagnosis of placenta previa: (a) failure to visualize the placenta in the body of the uterus; this suggests central placenta previa; (b) location of mass of placenta below the equator of the uterus; (c) widening of sacral promontory-fetal head distance when the placenta is implanted on the anterior wall; (d) widening of symphysis pubis-fetal head distance when the placenta is implanted on the anterior wall; (e) widening of the vesicocephalic distance seen after pneumocystography; (f) lateral displacement of the bladder seen after pneumocystography; (g) displacement of the fetal head from the midsagittal and sagittal planes.

March Fracture.—Tyner and Hileman observed between April 1941 and June 1943 166 cases of march fracture of the metatarsal bones. All current theories concerning the production of march fractures give due importance to the small repeated traumas incurred in long marches, but all authors agree that some other factor must be involved. "Physiologically inadequate" feet, abnormal length of metatarsals, overload, neurogenic influences, inflammatory processes and the handicap of a previously sedentary occupation of the patient have been mentioned as possible causative factors. The authors evaluated these possible causes in their cases. The most frequent site of fracture was at the distal third of the third metatarsal. The age distribution appears closely correlated to the age distribution in the Army and is therefore not considered of significance in the etiology. No neurologic disturbances or infections could be discovered. Prior occupation and length of service were studied in 20 cases. The duration of training time spent taking long hikes and forced marches averaged twenty-seven weeks. The patients' former occupations ranged from coffin making to dress designing and did not appear of significance. The 20 men who were interviewed personally reported that they had completed several miles of marching and that muscle fatigue had set in before the onset of symptoms. Studies on the blood chemistry of 12 patients revealed that the serum phosphatase levels averaged 648 units. This slight increase may be due to the stimulus of healing fractures. It is apparent from these studies that age, previous occupation, neurologic disturbances, bony anatomy of the feet and bone metabolism cannot be important etiologic factors. The authors think that due consideration has not been given to the fact that bones cannot stand great stresses unless they are adequately supported by muscles. When muscles of the foot and leg are fatigued, the weight of the body is thrown directly on the metatarsal bones, while the arches are flattened by the loss of muscular tone. All of the 20 men concerning whom information was available experienced fatigue before the pain of fracture occurred. This makes the authors believe that muscle fatigue as it occurs during long marches is the principal cause of march fractures.

Parathyroid Tumors and Hyperparathyroidism.—Alexander and his associates present the histories of 14 instances of hyperparathyroidism due to functioning parathyroid tumors which were treated at the Mayo Clinic up to November 1942.

In 2 cases there was fatal termination, while in 12 the results of operative treatment were excellent. The authors stress the widely divergent clinical pictures which may be presented by patients with hyperparathyroidism. No single symptom or sign should be regarded as decisive. Single findings of concentrations of calcium less than 12.5 mg. per hundred cubic centimeters of serum were encountered in 4 of the 14 cases of proved hyperparathyroidism. The authors stress the importance of the relation between the serum protein level and the serum calcium level. Depression of the value for serum phosphorus, measured as inorganic phosphate, is the rule in cases without gross impairment of renal function. The serum alkaline phosphatase level is elevated in proportion to the degree of involvement of bone. The Sulkowitch test provides a rough estimate of the presence or absence of excess urinary excretion of calcium. Considered alone it is not diagnostic of hyperparathyroidism. Bone changes in hyperparathyroidism appear to be an index more of the duration of the disease than of its severity. The incidence of renal lithiasis in hyperparathyroidism is about 60 per cent. In 13 of the 14 cases the tumor showed cytologic evidence of cancer. No correlation was found to exist between the weight of the tumor and the degree of hyperparathyroidism as measured by the concentration of calcium in the serum before operation. The average weight of the tumors was 18.2 Gm. They were encapsulated and usually were brown. Four were in the mediastinum, 3 being posterior and 1 anterior. Cytologic evidence of cancer was seen in chief cells, oxyphil cells and foam cells. Such evidence included irregularity of size and staining power of the nuclei, a densely staining chromatin network, giant nuclei, mitotic figures, pathologic mitoses, prominent nucleoli, irregular cellular arrangement and invasion of the capsule and blood vessels by tumor cells. The type of cell predominating in the tumor did not appear to affect the clinical picture. The authors stress the necessity of complete operative removal of parathyroid tumors.

Instilling Amniotic Fluid at Close of Operations.—Merkle points out that one of the chief functions of amniotic fluid in its natural location is to prevent adhesions between the amniotic sac and the fetus. He describes 27 abdominal operations in which amniotic fluid concentrate was instilled intraperitoneally immediately before the peritoneum was closed. Instillation in the first 8 cases was attempted by the funnel and catheter method, the fluid reaching the peritoneum by gravity. In the remaining cases the fluid was instilled through a specially designed trocar, positive pressure being substituted for gravity. The latter method proved preferable.

Localized Atrophy of Subcutaneous Fat After Repeated Injections of Grass Pollen. N. Francis.—p. 344.

Psychiatric Studies in Clinical Allergy.—Brown and Goitein discuss the psychiatric components of allergic personality. The authors demonstrated the existence of a special type of personality prone to asthmatic attacks. A sample population of asthmatic subjects and an equal number of nonasthmatic allergic subjects were classified for normal personality variables. The asthmatic patient had a somewhat greater tendency than the normal to be left handed and to marry and was subject to emotional instability when compared either with other allergic patients or with the normal population of the same age and social group. All the patients seem to be of average intelligence; but in 43 per cent the personality deviated from the normal and showed trends constituting abnormal or psychiatric

personalities. The abnormal aspects of personality were now tested for by an independent technician. The neurotic elements of deviation were determined separately by a psychiatric assessment of the patient and his background. This gave a score which indicated the degree of severity of the attendant neuroses. Psychiatric inquiries differentiated an abnormal personality of a special stamp (obsessive and paranoid). Neurotic and emotional maladjustment was discernible in 43 per cent of the asthmatic subjects as compared with 10 per cent in the control patients and 47 per cent in the allergic nonasthmatic subjects. Current neuroses were diagnosed in 20 per cent of the patients. The neuroses in allergic nonasthmatic patients totaled 16 per cent. These neuroses took the form of hypochondriasis, obsessionalism, conversion and anxiety-hysteria and (among the allergic nonasthmatic patients) vague anxiety symptoms, depression, obsessionalism and hysteria. In both groups the emotionally stable section admitted to a feeling of improvement as a result of physical treatment and seemed less inclined to mental resistance and obstinancy. They lacked the sense of dissatisfaction which was noted in the unstable section. The hysteroid type was more evident in the allergic neurotic patients and the obsessive type among the asthmatic neurotic patients.

Treatment of Scarlet Fever.—Three types of therapy for scarlet fever are available: (1) chemotherapy with sulfonamide compounds, (2) administration of commercial antitoxin and (3) administration of convalescent serum. Fox and Gordon evaluate these methods in an analysis of results obtained in 7,500 scarlet fever patients hospitalized at the South View Hospital in Milwaukee during the years between 1937 and 1943. Sulfonamide compounds find their chief value in the treatment of certain complications. These drugs are of no value in the management of the toxic phase or type of scarlet fever. The use of commercial antitoxin, prepared with horse serum, combats the toxic phase of the disease but introduces the danger of foreign protein reactions. Pooled human convalescent serum produces rapid clinical response and offers the best means of therapy. Of the 7,500 patients, 1,000 had received pooled human convalescent serum. To evaluate the effect of serum therapy, 1,000 consecutive cases were chosen from the hospital records for comparison. These control cases were deliberately selected from the year 1923, when only symptomatic treatment could be used, since antitoxin, convalescent serum and sulfonamide com-

pounds were not then available. The series of 1,000 patients of 1937 to 1943 contained a far higher percentage of seriously ill persons than did the 1,000 patients of 1923. Eighty-eight and six tenths per cent of the patients treated with serum were severely ill, in contrast to only 20.3 per cent of the control series. Notable beneficial effects of pooled convalescent serum included prompt subsidence of fever, alleviation of signs and symptoms, avoidance or improvement of complications, shortened period of hospitalization and lower mortality rate. The last mentioned consideration is especially significant in view of the fact that the lower mortality rate was obtained in a group of patients who were more severely ill. Smaller doses of convalescent serum than have been previously used have been found to be effective.

Ménière's Syndrome.—Atkinson maintains that in cases of idiopathic Ménière's syndrome one of two vascular mechanisms is at work, a primary vasodilator and a primary vasoconstrictor mechanism. These two groups can be differentiated by means of an intradermal test with histamine. The treatment appropriate to one group is inappropriate and deleterious to the other. Therefore accurate grouping is a prime requisite for effective therapy. The satisfactory results obtained by desensitization to histamine in the primary vasodilator group have already been published. This paper is concerned with the treatment in the primary vasoconstrictor group. The series reviewed comprises 110 patients observed between January 1940 and June 1943. All have been under personal observation. They have the idiopathic syndrome, they were proved to be insensitive to histamine and thus belong to the primary vasoconstrictor group. The author found nicotinic acid to be the most effective vasodilator drug. Its action is at the periphery of the vascular system. This distal effect is wanted, since it is the circulation in the capillaries of the stria vascularis which is believed to be at fault in this condition, at least as far as concerns the aural manifestations. It is essential to use nicotinic acid, not nicotinamide. Whereas the two substances are interchangeable as regards their vitamin effect, they are not interchangeable as regards vasodilator effect. The most efficacious method is to start with injections and gradually wean the patient to oral medication. The author discusses the indications for the intra-

venous, the intramuscular and the oral medication. The 110 patients were treated medicinally exclusively with nicotinic acid. The attacks of vertigo were relieved or greatly modified in 84 per cent of the cases.

Hereditary Hemorrhagic Telangiectasia (Osler's Disease).—Stock defines hereditary hemorrhagic telangiectasia as a rare disease, probably due to mesenchymal dysplasia, which is characterized by the presence of multiple acquired angiomata or telangiectasis of varying distribution and number with a tendency to bleed spontaneously or from slight trauma. It is transmitted as a dominant characteristic. The initial symptom usually consists of abnormally profuse epistaxis beginning at about puberty. This is followed by the development of multiple telangiectasias of the skin and mucous membranes from the age of 25 to 35. All symptoms tend to reach their greatest severity during the fourth decade. The author presents a review of the literature from 1933 to 1944 and adds 7 cases, which were gathered during the past two and a half years in his own otolaryngologic practice. In about 20 per cent of the recorded cases the disease probably developed in the absence of a family history. Whether these patients can transmit the disease to their progeny is not known. The author adds to the literature the third recorded instance in the last eleven years in which the disease can be traced through six generations in one family. The extreme rarity of this, together with the fact that the disease has become progressively milder during the last two generations in this family, suggests self limitation of the hereditary transmission. The disease is generally regarded as simple ectasia of preexisting vascular channels, but it is not improbable that the lesions are actually multiple acquired neoplastic angiomata arising from endothelial rests of embryonal origin. This is suggested by the following observations: Epistaxis usually predates the development of visible mucosal or cutaneous lesions; satellite lesions develop in the region adjoining the site formerly occupied by angiomata destroyed by treatment; the lesions have a universal distribution and some are of great size; they have a tendency to disappear spontaneously while new angiomata appear; the microscopic and biomicroscopic pictures suggest neoplastic development; there is a slow and incomplete but definite response to roentgen therapy. The newer methods of treatment include electrolysis, roentgen or radium irradiation, microinjection of sclerosing solutions and parenteral administration of moccasin venom. The author observed good results in the single patient who was treated with roentgen rays by the "intermediate" method. The literature includes many references to a possible relationship between Osler's disease and other diseases due not only to possible mesenchymal but also to possibly associated ectodermal dysplasia. These postulates have not been proved. The author thinks that more widely disseminated knowledge of the disease will result in its more frequent recognition and diagnosis.

Vitamin C-Sulfonamide Compounds in Healing of Wounds.—Ruskin reviews the literature on the role of vitamin C in the healing of wounds. He believes that the local effect of the ascorbic acid is independent of the systemic level of vitamin C. Vitamin C locally applied to wound tissue presents an additional factor in healing. The relationship of ascorbic acid to the bacteria in the wound area has been investigated, and the conclusion has been reached that ascorbic acid serves as a detoxicating agent. The possibility of using vitamin C in chemical combination with the sulfonamide drugs opened up a most interesting avenue of investigation. The chemical properties of ascorbic acid are such as to reduce the alkalinity of the sulfonamides. The vitamin also lends a hygroscopic factor which tends to prevent caking of sulfanilamide, thus prolonging uniform absorption. In order to have visual control of the advantages of the sulfonamide ascorbate, the drug was used in chronic, nonhealing wounds of long standing, in which bone would particularly be involved. Such easily visualized wounds involving bone are found in unhealed cavities following radical mastoidectomies and in ears with chronic suppurative otitis media and defects of the drum membrane. The routine procedure was to irrigate the ear cavity, dry the area and then fill the mastoid cavity, the middle ear and the external canal with the sulfanilamide ascorbate. The author presents a number of cases which indicate that sulfanilamide ascorbate and sulfathiazole ascorbate both stimulate healing with epithelization.

Dermatitis of Feet and Hands Due to Rubber.—Rubber dermatitis of the feet most often affects women, as rubber is used extensively in the manufacture of women's shoes. Rubber cement is used for basting the shoes during the sewing process and for fastening down the sock liner to the inner sole. An elastic rubber fabric is used frequently as an inner lining. The dermatitis may be manifested by erythema, edema, vesiculation, weeping and crusting. It may involve any part of the foot. However, it most frequently appears first on the toes. The sides of the heels are also early sites. Rubber dermatitis of the feet should be suspected when the patient has had a previous dermatitis from rubber girdles, dress shields and garters. There may be confusion with acute dermatophytosis of the feet. Physicians suffering from an eczematous dermatitis of the hands and feet are occasionally subjected to futile treatment for dermatophytosis when actually suffering from surgical glove dermatitis and rubber dermatitis of the feet. Sensitivity to rubber gloves should not be ruled out until patch tests have been performed on the back of the hands. The treatment requires elimination of exposure to rubber, which may prove difficult and, especially in women, may necessitate the purchase of custom built shoes in which all rubber has been eliminated.

Streptococcal Epidemic in Children's Surgical Ward.

—An epidemic of streptococcal infections in a surgical ward of a children's hospital provided material for study by Doyle and Chant Robertson. The ward admitted surgical patients from 2 to 5 years of age. The ward was overcrowded at the time of the epidemic. Most of the beds were separated only by a small table 20 inches wide, and the children could exchange toys with ease. Close contact of patients due to overcrowding of the ward, the presence of infected attendants, inadequate washing facilities and the presence of hemolytic streptococci in the air were the important factors. The epidemic was checked by removing all those with positive throat cultures, closing the ward to admissions and visitors, using flannellette masks and separate gowns in attending each patient, spacing the beds 9 feet apart, providing adequate washing facilities for the personnel, using a reliable hand antiseptic and wet mopping the floor instead of sweeping. A negative Dick test did not indicate immunity to scarlet fever caused by this strain of hemolytic streptococci. The advantage of a more rapid method of typing hemolytic streptococci became evident during the course of this investigation.

Trial of Dysentery Toxoid (Shiga) in Human Volunteers.—In a previous report Farrell and his associates presented laboratory and clinical data which suggested that the experimental product dysentery toxoid (Shiga) was antigenic and

safe for human use and would afford a reasonable hope of protection against dysentery caused by *Bacterium shigae*. The present report describes the reactions of 142 persons who received 1 to 4 doses of 0.25 or 0.5 cc. of the toxoid at various intervals, or a total of 377 injections, and sets forth the results of titration of antitoxin in 215 samples of blood taken from 100 persons at different stages in the process of immunization. Three groups of persons received 3 injections at intervals of ten, twenty-one and forty days respectively, and the ten day group received a recall dose three months after the third dose. The reactions to the injections, both local and systemic, were of the same order as those to the combined antigen T. A. B. T. Provided due caution is observed in the proper testing of the toxoid in laboratory animals, it would appear that a field trial of this material could be undertaken without undue concern. The antitoxic response was strikingly better after 3 doses than after 2. Long intervals between doses were advantageous, but the differences were not great.

Heart Disease in School Children.—According to Williams and his collaborators, heart disease ranks high as a cause of death among children over the age of 5 years. In national figures for the year 1939 heart disease was second to accidents as a cause of death in the age group 10 to 14 years. The figures for the state of Delaware indicate the same tendency. For the entire age span from 5 to 19 years heart disorders caused more deaths than any other condition except accidents. Examination of the hearts of 2,990 children of Kent and Sussex counties in Delaware disclosed 22 children with clinical evidence of organic heart disease, a prevalence rate of 0.7 per cent. Of this group of 22 there were 9 with murmurs characteristic of congenital heart disease and 13 with evidence of rheumatic heart disease. The latter condition was fairly evenly distributed between the children of the elementary and high schools but was somewhat more frequent in the Negro than in the white children. Arrhythmias consisting of 6 cases of extrasystoles and 1 of bradycardia were discovered. A group of 59 additional children had slightly abnormal cardiac sounds which were designated as accidental murmurs. The survey suggested the need for a program for the supervision and care of these children with heart disease. Such a program would include the following activities: 1. Case finding, with reports from physicians of cases of heart disease or rheumatic fever. 2. A central file of the records of these children. Such a file has already been started for records of children found in school surveys. 3. A consultation service with a thorough examination of children suspected of having heart disease. 4. Adequate care of acutely ill children to include beds for those requiring prolonged convalescent care. 5. Broad educational programs for instruction of nurses, physicians and the public in the problems of heart disease, the dangers of rheumatic fever and the methods of care.

Inactivation of Influenza Virus by Mild Antiseptics.

—Dunham and MacNeal reported studies on the action of bactericidal agents on the vaccinal virus. The tests were performed by injecting mixtures of the viral suspension and antiseptics into embryonated eggs. A similar technic, with modifications, was employed in the present study on the influenza virus. A number of antiseptics were tested for their inactivating effect on the virus of influenza during a brief period of exposure. This was accomplished by preparing mixtures of the antiseptics and virus, allowing them to remain in contact for three minutes, diluting the mixtures to the point where they would not be toxic for chick embryos and then injecting the material into embryonated eggs. Survival of the embryos indicated inactivation of the virus. The following preparations were found to inactivate the virus in three minutes or less: phenol, 3 per cent; tincture of iodine, U. S. P. XII, 0.1 per cent; Lugol's solution, U. S. P. XII, 1 per cent; mercury bichloride, 1:1,000; potassium permanganate, 1:1,000; copper sulfate, 1 per cent; propylene glycol, 90 per cent; liquor antisepsicus, N. F. VII, 80 per cent.

Pyridoxine Hydrochloride in Diseases of Nervous System.—Stone administered pyridoxine hydrochloride intraspinally to 26 patients with various disturbances of the nervous system. The average dose was 30 mg for children and 50 mg. for adults, with one to four injections per patient. It was well tolerated by all of these patients, and no untoward reactions were observed following its use. In a case of Sydenham's chorea of long standing, complete disappearance of choreic movements followed three injections of 50 mg. of pyridoxine at weekly intervals. In 2 other cases great improvement was observed following administration of a single dose of 50 mg. In 2 cases of infectious meningomyelocarditis and 1 case of anterior poliomyelitis, relaxation of muscular rigidity, some improvement in muscle strength and increase in range of passive and active movements became apparent within twenty-four hours after intraspinal administration of 50 mg. of pyridoxine. It hastened

recovery in a case of Korsakoff's disease which failed to respond to prolonged intramuscular and oral vitamin therapy. It also produced disappearance of pain and limitation of leg extension in a case of sciatic neuritis of unknown etiology after two intraspinal injections of 50 mg. at a weekly interval. Reduction of spasticity, improvement in gait and decrease of hyperreflexia were observed in a case of multiple sclerosis and a case of spastic paraplegia of unknown etiology following a single injection of 50 mg. In cases of dementia paralytica and the tabetic form of dementia paralytica the improvement was manifested in increased alertness, improvement in the sense of well-being, better coordination and improved ward behavior. Pyridoxine appeared to be of value when combined with intraspinal thiamine hydrochloride and artificial fever therapy. The favorable results observed in this small group of cases would seem to indicate that pyridoxine hydrochloride when administered intraspinally is an important adjunct in the treatment of postinfectious states and degenerative diseases of the nervous system, either when used alone or in combination with other vitamins or other methods of treatment.

Sulfadiazine in Influenzal Meningitis.—Sako and his associates report that 16 of 23 children with influenzal meningitis given sulfadiazine have been discharged as cured and have remained well. One patient developed and still has a residual generalized spasticity. Six fatalities occurred, all in infants below 8 months of age. There was only 1 recovery in the group of infants under 8 months of age. No fatalities occurred above the age of 8 months. Since sulfadiazine alone does not seem sufficient for young infants, it is imperative that type specific rabbit antiserum be given together with large doses of sulfadiazine. In older infants and children the recovery rate is high with sulfadiazine alone. Few spinal punctures and drainages were performed. Leukopenia in 1 patient, hematuria in 1 and drug fever in 1 were the only toxic conditions encountered that can be attributed to the drug.

Treatment of Hyperthyroidism in Children.—Recent controversy regarding the treatment of toxic diffuse goiter in children induced McIntosh to review the records of the children with the disease who were treated at the University Hospital

of Iowa City between 1925 and 1943. All of the 23 children were girls ranging in age between 7 and 16 years. Nineteen of the patients were subjected to subtotal thyroidectomy and 4 were treated without surgery. In the group of children operated on were 9 complete arrests, 3 nearly complete arrests, 5 recurrences and 2 deaths. The patients not operated on were all successfully treated by conservative management. The medical management of the 4 patients was not the same in all cases. All of them received bed rest during the period of hospitalization. Each also received phenobarbital sedation, the dose being regulated symptomatically. A high caloric and high carbohydrate diet was insisted on in each case. Lugol's solution was given to 3 children. The other child received no iodine therapy. Roentgen therapy was used in 2 instances after medical treatment alone appeared to be inadequate. The average period of time for the treatment of the patients operated on was six weeks, while that of those not operated on was seven months. Children deserve an adequate trial of medical management before surgery is advised, and for a considerable number of them surgery is neither necessary nor desirable.

German Measles During Pregnancy and Congenital Ocular Defects.—Rones presents histories of 4 infants whose ocular defects lend support to the claims of Australian observers that exanthematous disease in the mother during the early months of pregnancy can result in congenital ocular abnormalities in the child. Three of the mothers had had rubella and 1 had had morbilli. In the 2 cases in which the exanthem occurred during the second month of pregnancy the infants had cataracts, while in the 2 with the disturbance in the third month congenital glaucoma was present. Not all cases of congenital ocular abnormalities are due to an exanthematous disease in the mother during pregnancy. Many other factors can operate to produce such disturbances. More cases will have to be compiled before the occurrence of exanthems in the mother and ocular defects in the infants are accepted as causally related rather than coincidental. Rubella has been regarded as one of the most innocuous of the exanthematous diseases. We are now

faced with the fact that the virus attacking a pregnant woman before the placental barrier has been developed can cause a disturbance to the developing fetus, and particularly to the optic buds.

Pemmican.—Stefansson reviews the history of dried meats and of pemmican in particular. To make pemmican the Indian removed every trace of fat, split the lean into thin sheets and hung it up for wind drying. When thoroughly dry, the lean was converted into pounded meat. Bags were made of the hide of the animal in question (buffalo hide for buffalo meat, caribou for caribou meat and so on). These pillow size rawhide bags were filled loosely with pounded meat. Suet was then poured into the bag so as to percolate everywhere. The mouth was sewed up before the fat had time to harden completely and the bag tramped on or otherwise pressed so as to become flat, with a usual thickness of 6 or 7 inches. Pemmican seems to have kept as well in Oklahoma as in Manitoba. There are records of ten, twenty and more years in perfect condition. The author thinks that if our army used pemmican we could reduce by a third or half the weight and bulk of the meat element in a combination ration; with its nearly or quite exclusive use for certain purposes, we could reduce by a third or half the total weight and bulk of present special emergency or survival rations—such, for instance, as Army ration K, and we would have, from the start, a food which, in heat or cold, in moist or dry, is not experimental; an ancient Indian food that has been proved out by thousands of white users.

Primary Suture of Simple Mastoid Wounds.—Johnson and Spence report their experience in 44 cases of acute mastoiditis in which treatment was primary closure of the wound after the cavity had been filled with sulfonamide powder. The technical demands for primary suture are exacting. The mastoid exenteration must be complete. Great care should be taken to remove all infected cells. The perilabyrinthian cells are removed until the horizontal semicircular canal is sharply defined. The zygomatic area is thoroughly cleaned out, and in a number of cases the incus is brought into view. The mastoid cavity is then irrigated with isotonic solution of sodium chloride followed by thorough drying of the cavity. If any bleeding persists, epinephrine packs may be used to establish complete hemostasis.

The cavity is then filled with sulfonamide powder. It appears to make little difference in the end result which sulfonamide drug is employed. In more than half of the cases thus treated the mastoiditis complicated scarlet fever. In these it was possible to reduce the period of hospitalization from an average of fifty-two days to twenty-seven days. Patients without scarlet fever went home with dry ears, and the postaural wound healed in an average of fifteen days. At first patients were kept in the hospital longer than absolutely necessary in order to observe the effects of primary suture. Those admitted later were allowed to go home in fewer days. No serious complications were seen in primary closure, even in cases in which the sinus or dura was exposed. The temperatures promptly returned to normal after every operation, and no intracranial complications were noted.

Tularemia in New England.—Moore and his associates point out that New England appears to have been the last region in the United States to remain free of infection with *Pasteurella tularensis*, but now a total of 20 cases can be brought together. A chronological review of the New England cases is presented and 2 new cases are reported in detail. The first of these occurred in Massachusetts. A man aged 52 who had been bitten by an unidentified insect after three days began to notice occasional chilly sensations, fever and muscular weakness. Following a week of such symptoms he noticed soreness in the left axilla and a small papule at the site of the bite, which broke down and formed an ulcer. He poulticed the lesion and called in his physician, who gave him sulfadiazine for ten days. Since the fever and malaise persisted, as well as the ulcer and the sore node in the left axilla, he was referred to a hospital. Tularemia was suggested as a tentative diagnosis. A blood culture yielded no growth, and serum agglutination tests against *Pasteurella tularensis* were negative in all dilutions. The clinical course was one of continued swinging fever. A node developed in the right axilla and then generalized lymphadenopathy appeared. To obtain material to clarify the diagnosis, the ulcer was excised. The operative site healed cleanly, and the palpable nodes disappeared. Repeated agglutination tests for *Past. tularensis* were positive and the disease was now diagnosed as the ulceroglandular form of tularemia. The second patient, a man aged 36 from Rhode Island, four days prior to the onset of his illness had been hunting rabbits and had skinned and dressed them himself. He had a hangnail on the left thumb, and one day after the onset of the systemic illness the thumbnail became infected and the inflammation persisted despite treatment. For the eleven days until entry to the hospital this fever continued rising to 102 or 103 F. daily. Febrile illness with malaise, headache, cough and the infected thumb and axillary nodes continued. A diagnosis of ulceroglandular tularemia was made, and the possibility of pneumonic involvement was raised. Agglutination tests were positive against *Past. tularensis* in dilutions up to 1:80. Both of these patients recovered, but 3 of the 20 cases reported in New England have been fatal. The response of the Massachusetts patient to primary excision of the ulcer was striking, and if the results of this method are corroborated by other observers it may constitute a useful way of shortening the period of disability from the disease.

Fenestration Operations for Otosclerosis.—In a previous report Smith reported 32 cases of fenestration operation. About one third of these were successful. The results have greatly improved in the 53 additional operations reviewed in this article. The improvement in the results dates back to the new location of the fistula. In the first 18 operations of the total of 85 the fistula was made over the length of the external semicircular canal posterior to the amputated end, with the head of the malleus removed and the incus in its normal position. In the rest of the series, 67 in number, the fistula was moved forward over the dome of the vestibule anterior to the amputated end of the horizontal semicircular canal, with the head of the malleus and the incus removed. The results immediately were better. The fact requiring special emphasis is that in a vast majority of the cases of otosclerosis there is a gradual loss of hearing extending over a considerable time before there is a serious impairment of nerve function. It is during this stage that the operation offers the best chance for a successful and lasting result. If allowed to continue uninterrupted, the loss of nerve function will reach a point where the patient cannot be helped by the operation. The author performed the fenestration operation on 6 patients with severe loss in air and bone conduction. These patients submitted to the operation after being told the poor prospects. There were no successful results in these patients. The fact that there were no complications or deaths in the 85 reported cases prove that it may be performed without undue risk to the patient. It is dangerous in the hands of the untrained technician. The operation must first be taught on the cadaver, and the necessary time and effort

must be devoted to the correlation of the intricate steps comprising its technic before it is attempted on the living. The successful fenestration operation not only restores practical hearing but also checks the progress of otosclerosis.

Typhoid Outbreak Attributed to Contaminated Baked Beans.—Kleinschmidt describes an outbreak of typhoid resulting in 60 known cases in Toledo, Ohio, and 21 others in three counties in southern Michigan occurring in the months of June and July 1943. Epidemiologic investigation revealed the outbreak to be due to the eating of baked beans contaminated by a single chronic typhoid carrier living in Toledo. This outbreak established a new route of spread for typhoid and directed attention to the need for more careful health supervision of wholesale food establishments, especially those engaged in dispensing prepared foods. It emphasizes the necessity for continued effort to control typhoid carriers and illustrates the explosive potentialities of outbreaks of this disease despite a downward trend in its incidence and a condition of apparent safety, as might be inferred from current statistical observations.

- *Methods of Sanitizing Eating and Drinking Utensils. J. Andrews.—p. 1103.

Methods of Sanitizing Eating and Drinking Utensils.—Andrews reports the results of a comprehensive survey of eating and drinking establishments made in an Eastern city. Bacterial counts were made of plates, tumblers, spoons, forks and beer glasses. The lowest count reported, 2,800, was on spoons at eight soda fountains. The highest count, 7,000,000, was on beer glasses at nineteen barrooms. The next to the highest count, 390,000, was on tumblers at the eight soda fountains. Each figure is the average "swab count" of ten utensils. Rabbit blood agar was used for plating. These counts, all of which are greatly in excess of the standard of 100 organisms per utensil surface, show the need for improvement in dishwashing practice. On the average, lower bacterial counts are obtained with machine washing than with hand methods. However, the data do not justify the conclusion that manual methods should universally be discarded in favor of dishwashing machines. Satisfactory results can be obtained by either method. During the rush hour dishes will frequently be put

through the machine too rapidly to give proper washing and rinsing. Observations at one large cafeteria during the noon rush showed that for a group of ten consecutive racks of dishes washed one rack was in the machine for only twenty seconds, four for thirty seconds, three for forty-five seconds and two for sixty seconds. The shorter exposures are inadequate. One solution of this problem is to encourage the restaurant to have in use a large enough supply of utensils to tide over the rush period without having to make the dishwashing operation only a pretense. Frequently the person doing the dishwashing has not been instructed in the proper dishwashing technic and has not been impressed with the importance of his job. Since the outbreak of war, the problem of maintaining good sanitation in restaurants has been intensified by shortages of manpower and materials and increased customer loads. There are indications that the amount of disease spread in restaurants is increasing.

Analysis of 100,000 Examinations of Chest.—Zanca and Herpel present the results of routine examinations of the chest by the photoroentgen method in 100,000 consecutive selectees. Stereoscopic roentgenograms on 4 by 10 inch films have been found highly satisfactory, economical, easy to handle and process, susceptible of being rapidly interpreted with minimum eye strain and fatigue, and superior in definition to 14 by 17 inch films. The rejection rate for pulmonary tuberculosis in this series was 4.91 per thousand examined. This rejection rate applies to all types of pulmonary tuberculosis, from far advanced active cases with cavitation to the chronic minimal fibrous or apparently arrested cases in which stability of the lesions was not yet demonstrated. The low rejection rate for tuberculosis at this station reflects creditably on the splendid antituberculosis program in North Carolina over the last quarter of a century, also on the screening out of known tuberculous selectees at the local boards of origin.

Poliomyelitis.—Lubchenco and her associates review observations in 120 cases of poliomyelitis treated during the last six months of 1943 at the Children's Hospital of Denver. All patients with acute and convalescent poliomyelitis were treated by the Kenny method. The technic as described by Kenny could not be followed in regard to frequency of treatments. Ten to twelve packs plus physical therapy every day was impossible except for the most severe cases because of the shortage of help. Hot fomentations were applied four to five times a day to most of the patients. In the very seriously ill with respiratory difficulties, packs were given as often as three to four times every hour. When persistent and severe spasm was

present, ten to twelve packs a day were applied. During the acute stage some patients would wake up during the night and ask for packs, which gave them relief. Physical therapy was started as soon as it could be given without causing pain in the spastic muscles. This consisted of passive exercises to the "alienated" and paralyzed muscles and muscle reeducation of those muscles in which some power was present. Tightness which frequently followed spasm was treated successfully by stretching exercises. Physical therapy was administered three or four times a week. Accurate localization and early evaluation of muscle spasm and weakness is necessary if one is to use the Kenna method effectively. Thirty-two per cent of the patients were discharged as recovered. Of these, 12 per cent had no muscle weakness on admission. An additional 58 per cent showed improvement of varying degree. Ten per cent showed no change. Thirteen patients have had braces applied and 4 more are soon to receive them. Spasm in one or more muscles was present in all the cases. The average duration of spasm ranged from 92 weeks (neck) to 163 weeks (hip adductors). Patients received hot fomentations for an average of fourteen weeks. In 14 of 88 cases deformities developed despite hot pack therapy. The mortality rate was 58 per cent. All of the seven deaths occurred in cases of poliomyelencephalitis. The incidence of bulbar poliomyelitis was highest in those patients who had had operations in the mouth or pharynx. Three severe cases occurred within four weeks after tonsillectomy. One fatal case occurred two weeks after tooth extraction.

Endocrine Treatment of Cancers of Prostate.—Dean and his associates review observations on 100 patients with cancer of the prostate. These patients were treated either by castration or by the administration of diethylstilbestrol given in doses of 1 to 5 mg daily by mouth. Both forms of treatment have given striking clinical improvement at least temporarily. Pain is abolished, appetite is increased and a gain in weight results. After seven to eight months the patients are apt to have a return of pain and obvious progression of disease to death. Institution of other treatment, diethylstilbestrol for the castrated patients or castration of the patients treated originally with diethylstilbestrol, fails to affect the unfavorable course. Some patients continue to remain clinically free from symptoms of prostatic cancer for two years or longer. The number of such prolonged arrests of cancer seems more frequent in the group treated with diethylstilbestrol than by castration, so that this has become the routine initial form of treatment in the last eighteen months. Diethylstilbestrol seems to cause regression in the size of the prostate and reduction in the amount of residual urine more frequently than castration. Changes in bony metastases are toward an increase in calcification. Elevation of serum acid phosphatase above 1 Bodan's unit is pathognomonic

of prostatic cancer, although a low acid phosphatase does not rule out its presence. Serum acid phosphatase falls promptly in those patients who respond favorably to castration and rises again with a return of cancerous activity. The same changes occur more slowly in patients treated with diethylstilbestrol. Castration decreases estrogenic excretion in the urine and usually causes a rise in androgens as measured colorimetrically as 17-ketosteroids by the Callow-Zimmerman test. It causes a rise in excretion of pituitary gonadotropic hormones in the urine. The administration of diethylstilbestrol decreases the output of the 17-ketosteroids and the gonadotropic hormone from the pituitary. After its administration the excretion of diethylstilbestrol in the urine gives a great rise in the estrogen assays. These findings suggest that the mechanism whereby castration and diethylstilbestrol cause regression of prostatic cancers is fundamentally different.

Refrigeration Amputation.—Neller and Schmidt say that refrigeration was first applied at the Wisconsin General Hospital to a patient for whom, because of his extremely poor condition, no other therapy seemed to present a reasonable chance of success. This man, aged 65, entered moribund, with diabetic gangrene of the foot, gross infection, generalized sepsis and uncontrolled diabetic ketosis. The case was judged hopeless. Refrigeration amputation was performed and the result was so favorable that subsequently the authors used the method for 20 additional patients. All of them were poor risks, all had established gangrene, many had gross infection and general sepsis, were diabetic, and the average age was 68 years. The authors stress the importance of the proper selection of patients. Routine use of refrigeration is contraindicated. Patients requiring amputations who are not aged, who show no significant infection or general sepsis and whose general reserve is good are better managed under general anesthesia. Amputation for Buerger's disease should not be done under refrigeration because of (1) the vasospastic tendencies, (2) the lack of general toxemia and (3) the younger age level. Refrigeration amputation should be reserved for those patients who, because of senility, uncontrolled diabetes, infection, general sepsis or other complications would be poor risks for general anesthesia. Several different techniques are used, depending on the clinical picture. The authors differentiate between surgical refrigeration and preliminary control refrigeration and further divide surgical refrigeration into primary and secondary types. These may be used singly or in combination. Proper use of these different techniques will give best results.

Schick Reactions in Recently Confined Women and Their Infants.—Wright and Clark made Schick tests during the first five days after delivery on 250 women. Schick tests were also carried out at some time during the first five days of life on the infants of 145 of this group of women. The authors found that considerably less than half of the infants born to women living in a typical outer London suburb have an adequate congenitally acquired immunity to diphtheria. So infrequently do the mothers come into contact with toxigenic *Corynebacterium diphtheriae* that their circulating antitoxin concentrations fall to levels considerably below the critical titer for the Schick test. While a large proportion of the positive reactors among these recently confined women are themselves immune in consequence of the promptitude with which their antitoxin forming tissues respond to the secondary stimulus of the specific toxin, their low antitoxin titer during pregnancy confers little or no immunity on their infants. In the event of an epidemic rise in diphtheria two possible measures might be instituted. First, infants might be immunized considerably younger than is now the custom: this procedure has the disadvantage that very young infants seem to respond less well to prophylactic immunization than older infants or young children. Secondly, it might be desirable to immunize all Schick positive pregnant women during the latter part of the gestation period. Such a procedure would at the same time immunize any woman who was susceptible and raise the maternal antitoxin titer to a high level about the time of the birth of the infant.

Anemia Associated with Infection.—Saifi and Vaughan investigated hemopoiesis in acute and chronic infections. The peripheral blood picture was studied over varying periods in three different types of cases: (1) mild infections such as furunculosis, acne and sties, (2) acute infections of not more than three months' duration and (3) subacute and chronic infections of more than three months' duration. Patients receiving sulfonamide drugs in a bigger total dose than 1 Gm. have been excluded, since these drugs have an effect on hemopoiesis in

certain individuals. In the acute cases blood examinations were made every four or five days. In some instances reticulocyte counts were made daily. In the chronic cases the blood was examined at first every week and then every fortnight. A complete histologic study was made of the hemopoietic tissues in patients who died during the investigation. It was found that anemia was normocytic or microcytic in type, the color index never being above unity. A raised reticulocyte count occurred commonly in the chronic cases with severe anemia. In acute cases the reticulocyte count often rose when fever abated. Increased activity of the marrow was found in 12 of 15 cases examined, leukopoiesis predominating. There was no aplasia of erythropoietic tissue, primary erythroblasts and normoblasts being present with few mature red cells. The degree and character of the response appeared to be unrelated to the type of infection, the severity of the anemia or the age of the patient. It is suggested on analysis of the available evidence that anemia associated with infections is due to interference with the synthesis of hemoglobin.

Synergic Action of Penicillin and Sulfonamides.—The success which has attended the treatment of streptococci, pneumococci and gonococci infections in man with the sulfonamides has not been repeated when the infecting organism is the staphylococcus. Penicillin is much more potent against staphylococci than is the best of the sulfonamides, but, despite the susceptibility of these organisms to penicillin in vitro, treatment of human infections, even when continued for a relatively long time, often fails to eliminate the bacteria completely from the body. It seems to be almost a universal practice, when penicillin treatment is initiated, to abandon the administration of sulfonamides if they have previously been employed. Bigger records experiments in which the method used has been titration of penicillin, with or without sulfonamide, in broth or serum-saline in 5 cc. amounts, the test organism being usually *Staphylococcus pyogenes*. The tubes were observed after twenty-four hours or in some cases longer periods of incubation for evidence of growth of the bacteria inoculated. The presence of sulfathiazole in broth greatly increased the dilution at which the inhibitory action of penicillin on staphylococci could be demonstrated. Sulfathiazole was more effective in this respect than either sulfanilamide or sulfapyridine. The same synergic action of sulfathiazole and penicillin can be demonstrated in serum. The action of penicillin against *Streptococcus pyogenes* is similarly reinforced by the presence of sulfathiazole. It is suggested that this synergic action of sulfonamides and penicillin should be employed in the treatment of suitable infections in man.

Note on Thomas Splint C. A. Pannett—p. 180

Primary Tuberculous Infection in Nurses.—Daniels reviews data obtained through the Prophit survey, which was inaugurated in 1934 by the Royal College of Physicians of London under the terms of the Prophit bequest. Nurses form only one of the five groups studied in the survey, the others

being medical students, contacts, volunteer controls and boys in the Royal Navy training establishments. Since the outbreak of war it has been impossible to continue the work in the last two groups. Each person entering the survey is required to fill in a record card, giving information on age, environment, race, previous illnesses, history of contact and previous occupation. This information is supplemented by the results of an initial Mantoux test and an initial x-ray film of the chest. Each person is reexamined annually by Mantoux test and x-rays, and note is taken of any clinical illness during the period since the preceding test. It becomes possible then to analyze the progress of groups with different backgrounds and different states of tuberculin sensitivity under differing conditions of exposure. This report analyzes data collected on nurses. The total number of nursing entrants to the survey up to March 1943 was 3,764. Nurses were Mantoux tested and x-rayed shortly after entry to the preliminary training school. Of the 3,764 entrants, 50.3 per cent were positive to old tuberculin 1:10,000 or 1:100,000, 30.5 per cent were positive only to 1:100 or 1:1,000 and 19.2 per cent were negative. The rate of Mantoux conversion in the first year was 58.4 per cent and 78.3 per cent in two hospital groups. The group with a higher conversion rate had a high proportion of strongly positive reactions revealing conversion. Most had no notable symptoms between the last negative test and the first positive. A study has been made of the tuberculous morbidity in nurses who entered the survey before 1942 and whose chest x-ray film on entry was clear: 33 cases occurred in 452 nurses initially Mantoux negative, 43 cases in 2,120 nurses initially Mantoux positive. The 33 cases arising in nurses Mantoux negative on entry are briefly described. Analysis reveals the diversity of aspects of tuberculosis following primary infection in adults. In many cases it is difficult to determine whether the primary focus or a secondary infection is responsible for the lesion observed. The annual case rate per thousand was 7.4 in nurses Mantoux positive on entry and 18.8 in those Mantoux negative. The rate was particularly high in the first year after Mantoux conversion. The evidence of this survey, and the combined evidence of twenty other surveys, show that the risk of tuberculosis developing after primary infection in young adults is a serious one. It is suggested that a controlled method of antituberculosis vaccination is needed. In the absence of vaccination, recommendations are made with the object of reducing the primary infection rate, detecting primary infection when it occurs and reducing the tuberculosis morbidity.

Resuscitation of Battle Casualties.—Dick's transfusion unit dealt in eighteen months with over 800 shocked patients. Transfusion of blood and plasma was undoubtedly the major factor in the resuscitation of these cases. The total amount of fluid used was 1,776 pints (average per patient 3.54 pints), which included 1,327 pints of blood, 315 pints of plasma and 134 pints of saline solution. Usually the transfusion of 2 pints at a fast rate was sufficient to restore the blood pressure. If after this the response was only sluggish, it was found better to take the lesser risk of earlier operation. The average time spent in the resuscitation ward was about two to four hours. In practically all cases the transfusion was continued in the operating theater and often in the postoperative ward as well. Severe blood loss at operation was met by rapid transfusion, and on occasion a second separate transfusion apparatus was set up on another limb. With such a procedure it was not uncommon to give before, during and after operation a total of 10 pints of blood without any question of overloading the circulation. This method of continued transfusion is perhaps not widely enough appreciated, and there is a false belief that resuscitation is usually only a preoperative measure. There has been a good deal of controversy over the relative merits of blood and plasma in the field. The author mentions the deceptive appearance of recovery gained by plasma transfusion after severe blood loss. This fact, together with the undoubted efficacy of stored blood, was borne out in two invasions. In the first, no stored blood was available. The fresh blood was reserved for cases of extreme blood loss. For the moderately severe cases reliance was placed wholly on plasma, and it was found that the blood pressure was restored without difficulty, but again the pulse rate remained relatively high; also it was apparent that postoperatively the cases did badly. In the second

landing stored blood was available in quantity, but otherwise the conditions were similar. The results of transfusion in resuscitation were strikingly better and the condition of the patients after operation was much more encouraging. Reactions were fewer with stored blood than with plasma. With the blood, 5 per cent of the patients developed reactions in the form of slight or moderately severe rigors. With wet plasma the reaction rate was 7 to 8 per cent, but with the dry plasma this rate was around 20 per cent. Stored blood kept in good condition for at least twenty-one days in the refrigerator lorry, even during movement over rough roads.

Commonly Unrecognized Injury of Cervical Spine.—Walshe in 1936 with Ross reported cases of relatively mild head injury with associated damage to the cervical spine and spinal cord, in which the latter components had escaped notice during the period of treatment and had later been diagnosed under various titles as nontraumatic. Since then the author has observed further cases of this combined head and neck injury. The head injury is of the closed variety and is commonly mild. The injury involves a blow on the vertex or side of the head with an associated anterior or lateral flexion of the neck. The patient dives into shallow water, is thrown from horse or cycle, is flung out of a car or has fallen forward, striking the top of his head. In 1 case a sack of grain fell through an open hatch on the head of a man standing below. The mechanism of this cervical vertebral injury and its site of election between the fifth and sixth cervical vertebrae were described by Jefferson in 1928. The partial extrusion of the intervertebral disk has not been mentioned as a component of this injury, but in 1 recently observed case the narrowing of the relevant intervertebral space suggested that this had occurred. When he first comes under observation, still concussed or just recovering from concussion, the patient who has sustained this vertebral cord lesion is thought of as having head injury. The cord damage is not profound. "No one would listen to me when I complained about my arms" is the not rare later complaint of these patients. It is only when the patient is mobilized that the range of his disability becomes fully apparent to him and he may then find himself stiff and clumsy on his legs. Commonly he returns home and may even attempt to resume work. This he finds difficult. In a few weeks he notices that some muscles in the arms or hands are wasting, and he returns to his medical adviser. The condition is then labeled amyotrophic lateral sclerosis or disseminated sclerosis or, if a positive Wassermann reaction exists, the case is diagnosed as spinal syphilis. The clinical picture bears a superficial resemblance to motor neuron disease (amyotrophic lateral sclerosis, progressive muscular atrophy), yet the state of the tendon jerks in the arms, the persistence of paresthesias and the history suffice to make differentiation simple. The common failure to recognize this damage, with the subsequent tendency to erroneous diagnosis, may react unjustly on the sufferer's right to compensation. Some of these patients recover. Others remain with a fixed degree of disability, while yet others continue to deteriorate for some time as joint and muscle changes ensue.

Treatment of Ingrowing Toenails. T. E. Wilson.—p. 33.
Gas Gangrene at Australian General Hospital in Owen Stanley and Buna-Gona Campaign. K. C. Ross and W. P. Ryan.—p. 35.

Gas Gangrene in the Owen Stanley and Buna-Gona Campaign.—According to Ross and Ryan the Owen Stanley and Buna-Gona campaign was noteworthy for the relatively high incidence of anaerobic infection of wounds. During the four month period from Nov. 1, 1942 to Feb. 28, 1943 1,815 Australian battle casualties were treated and 82 cases of clinical gas gangrene occurred (4.5 per cent). Of these 82 patients,

12 died. Amputation was performed as often for the nature of the wound as for the extent of the infection. Exhaustion and emaciation contributed to the mortality. The clinical types ranged from the classic fulminating infection to cases associated with merely a local abscess around a retained missile. The latter cases with frank pus formation were diagnosed only by the presence of gas in the pus and by the growth of *Clostridium welchii* in culture. In 3 patients there was little evidence of infection in the wound itself, but an acute, overwhelming cellulitic edema spreading from the wound commenced four to five days after the receipt of the wound. In 2 of these cases the wounds were trivial. Death occurred in each case within forty-eight hours of the commencement of the edema. *Clostridia* were isolated from all. All patients with gas gangrene were given a full course of sulfanilamide. Polyvalent antitoxin was given to 51 patients in doses of 20,000 to 200,000 units, the usual dose being 50,000 units. It is difficult to assess the value of antitoxin, but the impression was gained that it had some beneficial effect. Forty-nine patients received transfusions of blood and plasma. The initial amount was usually 1 liter of blood and 1 liter of plasma. A full course of antimalarial therapy has to be given to patients receiving blood collected in a malarious area. One of the authors had success with radical excision in the Libyan Desert. Therefore it was decided to employ this wherever possible and to be conservative with amputations. At first, whether anaerobic infection was present or not, operations took the form of débridement and partial excision rather than radical excision; but the authors soon learned to rely more and more on radical excision, no matter how old was the wound. Excision caused little or no local or general reaction, and several partly excised wounds needed reexcision a few days later. The authors became convinced that the time factor did not matter, and with adequate resuscitation they excised the wounds as completely as the anatomic situation would allow.

 Submicroscopic Study of Human Bones by Diffraction of X-Rays. P. Lamarque and J. Mering.—p. 201.

Late Results of Roentgenotherapy of Glossoepiglottic Epitheliomas.—Baclesse differentiates epitheliomas of the oropharynx into two groups: (1) those of the lingual base and (2) those of the valleculae and of the epiglottis which develop in the space between the steepest part of the pharyngeal slope, the glossoepiglottic folds and the free edge of the epiglottis. This differentiation is of importance in statistical evaluation because in the first group the results have been much less favorable than in the second. The author reviews the results obtained in 256 patients with epitheliomas of the oropharynx which were treated at the Curie Foundation between 1920 and 1938 inclusive. The minimum period of observation was four years. The author takes into account the local extension, the lymph node invasion and the anatomic and clinical aspects. Among the 256 patients there were 89 in whom the cancer was still localized. Of these, 18 (20 per cent) were cured, whereas of the 167 patients with cancers which had already invaded adjoining regions only 5 (3 per cent) were cured. Classification of cancers according to presence or absence of lymph node invasion revealed that the percentages of cure were 16 in those without and 6 in those with invasion. From the anatomoclinical and radiographic points of view the author differentiates four types of glossoepiglottic epitheliomas: (1) the proliferating types, which extend on the surface, do not invade and extend toward the lumen of the oropharynx; (2) the ulceroproliferating type, which is likewise superficial; (3) the interstitial or infiltrating types and (4) the invasive types, which destroy the organ by ulceration. Of the total of 23 cured patients 16 had the proliferating type of cancer and 7 the ulceroproliferating type. None of the patients who had interstitial (infiltrating) or invasive cancers were cured.

 *Cholinesterase Content of Eye. R. Brückner.—p. 37.

Eye and Cholinesterase.—Brückner presents investigations on the presence and importance of cholinesterase in the eye, particularly in the aqueous humor and in the vitreous body. Studies on horses and cows revealed that cholinesterase is a regular constituent of the aqueous humor and it is assumed that this is the case also in man. The esterase found in the aqueous probably is derived not from the blood but from other sources. The esterase values of the vitreous body were occasionally lower than in the aqueous. In cows the concentration of esterase varied in the different parts of the vitreous; the concentration was greatest in the peripheral zones. The esterase of the vitreous body is probably derived chiefly from the retina.

 Abscess of Lung. A. S. Lentino.—p. 545.
 Use of Vitamin K. C. Morel.—p. 581.

Prothrombin in Preserved Blood.—Banfi and his collaborators found that the time of coagulation and the amount of prothrombin in preserved blood and preserved plasma do not change during the first three days of conservation. The coagulability diminishes slowly but continuously up to a point of final incoagulability of plasma conserved for five months and to which thromboplastin and calcium are added. The amount of prothrombin in the blood and plasma increases during the first three days up to double values in relation to the initial figures. This early increase of prothrombin in the blood and plasma seems to be due to rapid formation of the substance through its sensitization during the process of disintegration of platelets. After the third day prothrombin diminishes down to figures as low as 30 per cent in five months in relation to the initial figures. Transfusion of blood or plasma, when it is preserved for a certain time, is of no therapeutic value in controlling hemorrhage due to hypoprothrombinemia.

- *Pregnancy and Cancer of Cervix. C. Mönckeberg B.—p. 417.
 Quadruple Pregnancy. J. Di Bitonto and S. Wilber.—p. 465.

Pregnancy and Cancer of Cervix.—Mönckeberg B. encountered 20 women with cervical cancer among 36,500 pregnant women who were observed in a maternity ward in the course of ten years. All the patients but 2 were under the age of 40. All but 1 were multiparas. They complained of hemorrhage small or moderate, continuous or intermittent. Cancer was recognized during the last half of pregnancy in the majority of the cases. It was of the type of cellular epithelioma in 11 cases. The author advises local examination and biopsy as a routine in pregnant women complaining of hemorrhage during pregnancy. Pregnancy aggravates cancer of the neck, which in its turn predisposes the patient to abortion. Roentgen therapy and radium therapy are interdicted as dangerous for the infant. The author advises the following scheme: (1) Immediate hysterectomy followed by transpelvic roentgen therapy for women with operable cancer before the sixth month of pregnancy, (2) postponement of operation up to full term, abdominal cesarean section at full term and total hysterectomy followed by roentgen therapy and radium therapy in women with operable cancer beyond the sixth month of pregnancy and (3) abdominal cesarean section at full term, and subtotal hysterectomy followed by roentgen therapy and radium therapy in women with inoperable cancer before or after the sixth month of pregnancy.

Book Notices

Global Epidemiology: A Geography of Disease and Sanitation. By James Steiars Simmons, B.S., M.D., Ph.D., Brigadier General A. U. S., Tom F. Whayne, A.B., M.D., Lieutenant Colonel, M. C., A. U. S., Gaylord West Anderson, A.B., M.D., Dr.P.H., Lieutenant Colonel, M. C., A. U. S., Harold MacLachlan Horack, B.S., M.D., Major, M. C., A. U. S., and Collaborators. Volume One. Part One: India and the Far East; Part Two: The Pacific Area. Cloth. Price, \$7. Pp. 504, with illustrations. Philadelphia, London, & Montreal: J. B. Lippincott Company, 1944.

This is the first volume of what is no doubt a unique work in medical publication. As a part of the work of the Division of Medical Intelligence in the Bureau of Preventive Medicine in the Office of the Surgeon General, information regarding medical conditions in every area throughout the world has been assembled. The information is here coordinated and presented in such form as to be exceedingly useful to every one concerned with health in far parts of the world. Thus, for Burma there is a discussion of its geography and climate, of the organization of its public health services, its medical facilities, the diseases that are prevalent and the nature of their spread, with a good summary and a bibliography. The major problem of public health in Burma was malaria. Other important diseases are listed. Each of the nations investigated is given similar treatment. The book is handsomely printed in two columns, with large type and many exceedingly useful maps. This is a work of reference which should be available in every medical library and which will be found immediately useful by every physician concerned with disease in any of the nations covered. This is truly an "excursion" into the unexplored field of geomedicine. Now that airplanes have made every section of the world easily accessible, this book serves an immediate need.

Cataract and Anomalies of the Lens: Growth, Structure, Composition, Metabolism, Disorders and Treatment of the Crystalline Lens. By John G. Bellows, M.D., Ph.D., Assistant Professor of Ophthalmology, Northwestern University Medical School, Chicago. Cloth. Price, \$12. Pp. 624, with 212 illustrations. St. Louis: C. V. Mosby Company, 1944.

This book is a combination of laboratory and clinical investigations necessary to establish a basis for a more complete clinical understanding of the normal and pathologic crystalline lens. The literature has been thoroughly reviewed, and many theories are presented and discussed without an attempt being made to evaluate all of them. The author has attempted to give the essential scientific facts concerning the embryology, anatomy, histopathology and biochemistry of the lens before going on to the more interesting practical or theoretical conclusions which must be based on this material.

The early chapters are devoted to the comparative anatomy and histology of the crystalline lens. This is followed by a rather thorough discussion of the composition of the lens, which includes all the literature on the chemistry brought up to date. Many analytic tables are included. Thirty-two pages are devoted to the metabolism of the lens and capsular permeability.

The first five chapters with their numerous tables and condensations of many scientific laboratory reports will no doubt be boring reading for the average clinician, but the effort will well repay any ophthalmologist with an interest in getting below the surface of clinical case reports, as well as any anatomist, chemist or biologist who may have special interest in this important structure.

The last four chapters are of considerable interest to the clinical ophthalmologist. They include a comprehensive discussion on developmental defects of the crystalline lens and contain many case reports. Much space is devoted to cataracts due to radiant energy, electricity, deficiency of some vital constituents and toxins. The discussion on toxic cataracts is important, as such cataracts are being seen more frequently. The chapter on cataracta complicata contains reports of many unusual causes. Stress is placed on endocrine dysfunction as a cause of cataract. The discussion of senile cataract is complete and includes the operative treatment and complications of cataract surgery. This chapter should be of vital interest to the average clinical ophthalmologist.

Physiologic-chemical factors have been dealt with at length, although an attempt has been made to be both systematic and practical in proceeding from the development and growth of the lens to a consideration of its structure. After becoming

acquainted with the lenticular composition and metabolism, the reader should be well equipped to appreciate more fully the clinical problems presented in the last five chapters. The arrangement is such that a reader not interested in comparative anatomy, for instance, may pass on to parts of the subject which do interest him. The numerous illustrations are well chosen and contribute materially to the value of the book.

The author has produced an exceedingly interesting and important work, one which will take its place as the authority on the crystalline lens.

Industrial Medicine. Edited by Sir Humphry Rolleston, Bt., G.C.V.O., M.D., K.C.B., and Alan A. Moneriff, M.D., F.R.C.P. With an introduction by Air Vice-Marshal Sir David Munro, K.C.B., M.B., Ch.B. Cloth. Price, 16s. Pp. 202, with 5 illustrations. London: The Practitioner by Eyre and Spottiswoode, Ltd., 1944.

This is a handbook, as the title indicates, with various authors contributing chapters on industrial medicine and the general practitioner, industrial poisons, industrial dermatoses, chest disease in industry, miners' nystagmus, toxic anemia, the treatment of the injured workman, backstrain, neuroses in industry, malingering, nutritional problems related to industrial workers, adolescents in industry, fatigue and boredom, lighting problems, ventilation and heating, welfare services, the works ambulance room and factory law in relation to health and welfare.

It is stated in the preface that this book resulted from the interest shown in a small symposium on industrial medicine published in the periodical the *Practitioner*. The subject of each of the chapters apparently was selected on the basis of interest and need for information on these industrial medical problems in the British Isles, miners' nystagmus being prevalent there and nonexistent in the United States. The inclusion of eighteen major subjects in 183 pages makes this a compendium and a convenient reference for those becoming interested in industrial medicine. Because of its brevity, superfluous details are omitted to make it a highly practical book, as each author has handled his assignment ably. The introductory chapter on industrial medicine and the general practitioner, by Air Vice Marshal Sir David Munro, outlines the relationship that should exist between the practitioner and industry and workers, particularly as related to the general improvement of health in industrial areas.

The book should have wide usage by general practitioners because of its practicality.

A Six Year Journey. Published by Cleveland Child Health Association, Leyton E. Carter, Director of the Cleveland Foundation. Paper. Pp. 14, with illustrations. Cleveland, Ohio, 1943.

This is a report issued by the Cleveland Child Health Association of a project begun in 1937 dealing with preschool children. The study began when it was realized that children entering Cleveland's public school kindergartens showed an alarming number of physical defects, which could have been avoided with proper preventive work during the preschool years. There were approximately fifty organized school centers where the children received from almost no care to excellent care. The latter was given only at those centers where the parent paid a fee. There was no uniformity among these various centers. The association then defined through its standards committee the meaning of a "good nursing school." Through the efforts of this association the standards in all centers began to rise. There is now a great need for such centers, and this booklet will be of help to those groups that are planning to form and maintain such centers or schools.

The Experiments of Nature and Other Essays. By Irvine McQuarrie, Ph.D., M.D., Department of Pediatrics, The Medical School, University of Minnesota, Minneapolis. Delivered at the University of Kansas School of Medicine, Lawrence, Kansas. Porter Lectures Series XII. Cloth. Price, \$1. Pp. 115, with 16 illustrations. Lawrence, Kansas: University Extension Division, University of Kansas, 1944.

Three scholarly lectures delivered at the University of Kansas School of Medicine in 1942 are included in this book. The first lecture is entitled "The 'Experiments of Nature' and the Advance of Medical Knowledge." The second is on "Diseases of the Adrenal Glands in Children" and the third on "Impressions of Medical Conditions in Besieged China." They are all thoughtful and well illustrated. The first in particular is a well ordered plea for the more careful pursuit of scientific observation in clinical investigations.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

MAGNESIUM AND CALCIUM PHOSPHATE CALCULI

To the Editor:—What specific foods in the diet tend to the formation of renal magnesium and calcium phosphate calculi? What part does vitamin A have in the prevention of these formations? If important, what dosage is recommended?

Major, M. C., A. U. S.

ANSWER.—The oxidation of foods within the body results in the formation of an ash. Foods in which calcium, potassium, sodium and magnesium predominate over phosphate, sulfate, chloride and the uncombusted organic acid radicals are called alkaline ash foods. Since phosphatic stones form in urine, which usually has an alkaline reaction, foods which cause this reaction should be restricted. As a general rule, vegetables and fruits are alkaline in their final reaction within the body. As a prophylactic against formation or development of recurrent magnesium and calcium phosphate calculi, Higgins has recommended the high vitamin A acid-ash diet. Restriction of foods with high calcium and magnesium concentration has also been suggested. For more specific information see Renal Lithiasis by C. C. Higgins (Springfield, Ill., Charles C Thomas, 1943) and Dietetics for the Clinician by M. A. Bridges (Philadelphia, Lea & Febiger, 1941). Clinical and experimental evidence has demonstrated the relation between vitamin A deficiency and formation of renal calculi. A vitamin A deficient diet in the white rat for ten weeks usually produces keratinization of urinary tract epithelium, for example, of the kidney pelvis. Desquamation of the epithelium and keratinization may cause sufficient irritation to produce the initial lesion, while elaboration of fibrin forms a framework for deposition of crystalline sediment and subsequent development of a calculus. The daily requirement of vitamin A is estimated to be between 6,000 and 8,000 international units for the growing child and 6,000 international units for the adult. Biophotometer tests may be utilized in management of patients with renal lithiasis to determine the response to dosage administered.

MENSTRUATION AND CLIMATE

To the Editor:—I have a 17 year old patient who menstruates every twenty-eight days when the weather is cold and every fourteen to seventeen days as soon as the weather becomes warm. This is the third summer that it has occurred. The menses started at age 13 and have been regular otherwise. The flow is moderate for five days. What, if any, is the effect of climate on the menses?

Morris Weinstein, M.D., Irvington, N. J.

ANSWER.—There are many circumstances which can alter the periodicity of the menstrual flow. Among them are marriage, pregnancy and labor, change of climate, change of occupation, illness and mental or physical shock. The exact effect of climate on the menses has not been agreed on. Thus, while it is generally believed that in countries where the temperature is high most of the time the onset of menstruation occurs earlier than in countries of moderate or low temperature, this belief has not been definitely proved by statistics. Usually change of climate and change of temperature produce an amenorrhea rather than an alteration in the frequency of the menses. The case cited is unusual, but the occurrence does not mean that there is anything wrong with the patient. Treatment is not necessary.

SUTURES FOR HERNIOTOMY

To the Editor:—A few patients who have had recent herniotomies have told me that their periods of stay in the hospital were only one week. Apparently there have been no recurrences of the hernia. In order to discharge hernia cases so soon is there any special suture or unusual type of stitch required?

Ranson B. Baker, M.D., Rawlins, Wyo.

ANSWER.—Generally speaking, there are three types of sutures utilized in the repair of hernia: (1) the absorbable type represented by catgut, (2) the unabsorbable type represented by fine silk or cotton and (3) the fascial type. Most surgeons still adhere to the absorbable type, some preferring chromatinized catgut because of its slow absorption. The silk suture is probably more reliable but requires the mastery on the part of the surgeon of an especially fine technic as advocated by Halsted. Of late there has been a renewed interest on the part of some surgeons in the use of autoplasmic fascial repair. McArthur, Gallie and

LeMesurier advocated long ago the use of both living and dead fascial strips for the repair of inguinal hernia. They have demonstrated in experiments and from microscopic studies that autoplasmic suture heals and lives in situ; it is not absorbed and does not slough. McArthur's technic consisted in splitting a strip from the aponeurosis of the external oblique without detaching it, threading it onto a needle and accomplishing the Andrews imbrication operation with it. If one was to rely for his results on the suture rather than on the method, the autoplasmic fascial suture of McArthur is undoubtedly the most reliable. However, the technic is rather clumsy and difficult and time consuming.

Regardless of the type of suture used, the tendency is not to permit patients early rising after an inguinal herniotomy. The success of the operation depends on the proper healing of the coapted layers.

RESTAURANT SANITATION AND CHIPPED CHINA

To the Editor:—The Columbia County Department of Health is interested in promoting publicity for good restaurant sanitation. The elimination of the many and increasing number of cracked and chipped cups in our restaurants was one of our objectives. We hesitate to do anything further about this after seeing the August issue of Hygeia. On page 629 is a full page advertisement by the War Advertising Council with the title "The Chipped Teacup of the Patriotic Mrs. Jones." Is it your opinion that the danger of transmission of disease through cracked and chipped cups is of greater or lesser significance than the conservation of materials during wartime? We are trying in our community to maintain good sanitary conditions in spite of lack of materials and regret the appearance of this particular advertisement in the more popular magazines. While this particular advertisement relates to home use of cracked teacups, we believe it could easily be misinterpreted.

Sue Hurst Thompson, M.D., Hudson, N. Y.

ANSWER.—From the esthetic point of view the use of chipped or cracked table ware is to be discouraged. In the presanitary days, when but limited attention was given to cleansing and disinfection, the crevices of chipped dishes were packed with particles of food and living bacteria. While it is possible to sterilize chipped or cracked dishes, few eating places carry out adequate disinfection so as to eliminate the menace of the chipped utensil. Even though replacements are now difficult, most health authorities, for the protection of the people, prohibit the use of chipped table ware.

DISCOLORATION OF TEETH FROM ERYTHROBLASTOSIS FETALIS

To the Editor:—About two years ago I had occasion to see 3 newborn infants, not related, with erythroblastosis fetalis. These infants were given repeated transfusions of Rh negative blood until the hemoglobin and red cell count ceased to drop. They were dismissed from the hospital with an iron compound added to the daily formula. In all 3 infants the iron was discontinued several months before the eruption of the first teeth. When the deciduous teeth erupted they were all deeply discolored with a grayish green pigment which seemed incorporated in the tooth structure instead of being on the tooth surface. The teeth were otherwise normal and the babies have since developed normally physically. Can you give me any explanation for this discoloration? Is it related to the iron in the formula or to the erythroblastosis? M.D., California.

ANSWER.—The discoloration of the deciduous teeth in these cases probably resulted from erythroblastosis fetalis and was caused by excessive amounts of blood pigments that were deposited during the prenatal formation of the enamel and dentin of the deciduous teeth. The deposition of endogenous pigments in the enamel and dentin during their formation and calcification has been reported in uroporphyrin and in icterus neonatorum. It is possible but doubtful that the exogenous iron given during the postnatal period contributed to the pigmentation. In iron therapy the deposits of stain are present on the surface of the tooth rather than within the enamel and dentin.

ANESTHESIA FOR CESAREAN SECTION

To the Editor:—In Queries and Minor Notes in the July 29 issue of The Journal there is a question entitled "Anesthesia for Cesarean Section in Women with Myocarditis and Renal Disorders." Long experience has taught me that a great deal more anesthesia is given during the ordinary cesarean section than is at all necessary. In my service at the Graduate Hospital of the University of Pennsylvania the rule is to prepare the woman's abdomen and catheterize before any anesthesia is given. The anesthetic is started when everything is ready to make the incision. As soon as the patient is unconscious the incision can be made and the baby extracted under a wonderfully small amount of anesthesia. If this practice is followed, instead of anesthetizing the woman thoroughly before the abdominal preoperative preparation is made it will be found that the child does not have to be resuscitated—in fact, it cries just as readily as though the operation had been done under local or spinal anesthesia.

THE MAKING OF AN OPHTHALMOLOGIST

CHAIRMAN'S ADDRESS

CONRAD BERENS, M.D.

NEW YORK

In guiding the medical student who desires to practice ophthalmology or in advising the young ophthalmologist, stress should be laid on education, ethics, research and the importance of attending medical meetings.

Older ophthalmologists can be of great assistance to young men by merely setting a good example in clinical practice, by offering their assistance in training and by imparting the results of their experience. The question of the adequate training of the ophthalmologist seems to be especially important at this time because of the disorganization of educational opportunities and depletion of teaching staffs due to the war. Therefore this subject has been chosen for presentation. Certainly there has been excellent precedent in the Transactions of the Section¹ for this type of discussion.

EDUCATION

The medical curriculum of the ophthalmologist should include comprehensive courses in higher mathematics, biology, chemistry, physics, modern languages and, if possible, elementary courses in embryology, comparative anatomy, physiology, bacteriology and physiologic chemistry. In medical school the student should be permitted to elect certain subjects which will aid him in ophthalmology. For example, he should be encouraged to devote more attention to clinical ophthalmology than to clinical obstetrics. He should have a keen interest in the fields closely related to ophthalmology and have the privilege of continuation studies in fundamental work, particularly anatomy, embryology, pathology and immunology in relation to ophthalmology. This statement should not be construed as suggesting that the ophthalmologist's training should not be as broad as possible in general medicine but merely that some time should be available for elective studies.

After graduating from medical school there is a question of a general hospital internship. Some ophthalmologists consider this period of training a waste of time. However, the stimulation and broadening influence derived from close association with and observation of the work of the great leaders in medicine and surgery makes a general internship the most impor-

tant part of a man's medical training. A hospital where the young physician can obtain stimulation from outstanding clinicians and teachers should be his first choice. Although the American Board of Ophthalmology and most of the states require only one year of training in a general hospital, I believe that from eighteen months to two years is not too much time for the ophthalmologist to devote to this part of his training and that the major part should be devoted to internal medicine. It is regrettable that our medical students today are to have only nine months of general hospital experience and that the Army has been unable to arrange for some degree of selection of the medical school by the applicant.

The next step is usually a residency of two or three years in an eye hospital or eye department of a well equipped general hospital. During this period of training the ophthalmologist acquires by apprenticeship proficiency in the technics of operations and methods of treatment and learns to use his hands under the guidance of experienced surgeons. The clinical judgment acquired by experience aided by apprenticeship under a good clinician may be even more important than surgical technic. One of the best and most valuable parts of an eye resident's hospital training is that received from his senior resident; the young ophthalmologist should make rounds with him and observe and write his notes. In doing this he will profit greatly, as will hospital records. Unfortunately in peacetime there are not enough residencies in the country for all young ophthalmologists to receive this type of training. Therefore other means of training must be provided, for example, working in a clinic or in an office with an ophthalmologist who is a good clinician and who keeps adequate records.

If possible the student should have a course in the basic sciences related to ophthalmology before he enters active hospital work. He should work toward an advanced degree and should be stimulated to undertake a specific research problem and prepare a thesis preferably while he is having basic science training. My observation leads me to believe that men so trained make better residents and benefit more from their special hospital training. If it is not feasible to obtain a course in the basic sciences, one should attend lectures and demonstrations by members of the hospital staff, attend meetings of ophthalmologic sections and enroll in the Home Study Course sponsored by the American Academy of Ophthalmology and Otolaryngology under the direction of Dr. Harry S. Gradle.

The education of war veterans presents a special problem. Many of our young men have been called into the military services in the middle of their hospital or basic science training. Even before the President's message to Congress concerning the postwar education of veterans for from one to three years, ophthalmolo-

¹Read before the Section on Ophthalmology at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 14, 1944.

²I. Knapp, A.: Importance to the Practicing Ophthalmologist of Contributing to Literature. Tr. Sect. Ophth., A. M. A., 1926, p. 17. Todd, J. C.: Research in Ophthalmology and the Training of Ophthalmologists. *Ibid.*, 1914, p. 17. Holloway, T. B.: The Correlation of University Research. *Ibid.*, 1930, p. 17. Greenwood² Snell² Nickel²

gists, guided by suggestions made by Dr. Gradle, have been planning for the teaching of ophthalmology to physicians released from our armed services. The instruction will be given with little, if any, cost to our confrères who have sacrificed so much for those of us who remained at home. The undertaking of the entire expense by the government may or may not be desirable and should be carefully studied.

ETHICS

While ethics may be taught by lectures, the conduct of older ophthalmologists provides the greater stimulus. Several of our chairmen have ably presented this problem in their chairman's addresses.² The county medical societies are influential in maintaining and raising ethical standards, especially when the higher type of physicians take an active part in the work of the society. The boards of censors of these societies act on complaints from other medical practitioners and the public concerning unethical actions of member physicians.

Young ophthalmologists as well as any physician should appreciate the importance of never detracting from the standing or the work of his confrères. A man's own position is never helped when he attempts to make himself important by belittling his colleagues. Another grave mistake is to speak disparagingly of large fees obtained by other men. If the fees are large but commensurate with ability to pay and the service rendered is of high quality and honest, colleagues should be delighted. To my knowledge no honest physician ever became rich through the practice of medicine, and physicians in private practice give more of their time to charity in one way or another than they can physically or financially afford.

ETHICS AND OPTOMETRY

One of the most important problems in ethics from the standpoint of public service and public health is that of optometry. Those who believe that optometrists should be taught certain subjects and that there should be closer cooperation between ophthalmology and optometry are apparently in conflict not only with the Oath of Hippocrates, "I will impart a knowledge of the art to my own sons and those of my teachers, and to disciples bound by a stipulation and oath, according to the law of medicine, but to none other," but also with certain resolutions passed by this section in 1936, which were reaffirmed in 1942. I believe this part of the Hippocratic Oath should be reconsidered by ophthalmologists in the light of conditions existing in 1944 and that the entire matter should be returned to the individual state and county societies.

Some members of the section have said that insufficient consideration has been given to optometry and that the only place where these problems have been discussed has been in the brief executive meetings of the section. These statements have been made without knowledge of the facts, for the Section on Ophthalmology appointed a committee on optometry as far back as 1913, designating Dr. William C. Posey as chairman. This question was thoroughly and ably discussed by Hiram Woods in 1913 and by Walter B. Lancaster in 1928 in their chairman's addresses. Having served as secretary of the American Committee on Optics and Visual Physiology and as a director of the National Society for the Prevention of Blindness, I have gradu-

ally accepted the conclusion that lack of cooperation between ophthalmologists and all others concerned with vision and eye health is the most serious unsolved problem in the prevention of blindness today.

Those who have been closely associated in the study of this problem believe, almost to a man, that optometrists should be taught by those best qualified to teach subjects which would aid in preventing blindness. A recent vote taken by the American Ophthalmological Society and by this section indicates a similar opinion among a large and growing group of ophthalmologists. I believe that a careful unbiased study of the reasons why so many men are now in favor of cooperation, by those who hold opposite views, would lead to a change of opinion in many cases.

The armed forces have used optometrists under the close supervision of ophthalmologists, and in the great majority of instances of which I have personal knowledge the arrangements have been mutually satisfactory to the ophthalmologists and to the optometrists. Because of this, ophthalmologists have asked whether a similar arrangement would not be satisfactory in private practice, as this association has also proved useful in some of the nation's municipal and private hospitals. This is one problem a special committee of the American Medical Association might well study to the mutual benefit of all concerned.

In spite of the existence of the 1942 optometry resolution, we should cooperate in preventing the introduction of bills in our state legislative bodies and the publication of articles in scientific or lay journals which fan the flame of a feud. The feud between the two groups concerned with eye care not only lessens the faith of the public in all types of eye service but also shakes public confidence in medical care in general, because few laymen can define the terms optometrist, ophthalmologist and optician.

I urge each young ophthalmologist and every member of this section to study this problem from the aspect of public health, service to the public and the prevention of blindness, without prejudice engendered by personalities or by financial considerations.

FEE SPLITTING AND PARTICIPATION IN THE SALE OF GLASSES

Several of my predecessors who have discussed similar subjects³ have had nothing to say on fee splitting for operations, drugs, x-ray examinations and hospitalization. However, I believe that this practice is so little indulged in by ophthalmologists in spite of one or two recent isolated examples that it may be dismissed. All ophthalmologists should strive to eliminate these practices by their example and by aiding American medicine in the fight against this degrading and dangerous evil practice.

Profits from the sale of glasses is another matter which cannot be too heartily condemned if money is received for no service rendered or no financial risk assumed. Undoubtedly in many communities ophthalmologists must dispense their own glasses, and if the lenses were sold without profit these ophthalmologists might be in unfair competition with the opticians and other persons associated with eye care, who could not afford to dispense glasses at cost. The ophthalmologist who dispenses his own glasses usually would prefer to find a reliable optician or encourage one to settle in his

community. Thus he could free himself from conducting a business which, if it continues for any length of time, frequently becomes a financial necessity.

It is my conviction that all those associated with eye care, who participate to any great extent in the sale of glasses, even though they perform a service in dispensing lenses and thus are able to charge low fees for their consultations, are in unfair competition with those who do not participate. Even when ophthalmologists or optometrists dispense glasses without profit, they are still in unfair competition with those who do not dispense their own lenses.

If when beginning practice the young nonparticipating ophthalmologist makes his fees low in order to permit him to compete with ophthalmologists and optometrists who do participate in the sale of glasses, it will later be hard for him to raise his charges. However, to start his practice with adequate fees may be so difficult as not to be practical. There is no question that it is preferable from the standpoint of the public and medicine to give honest, real medical service and charge for it than only to seem to give low cost service. Some of the plans for prepayment of medical service stress low fees for eye examination but neglect to mention profit from glasses. This tendency to cheapen the apparent cost of medical service by hidden profits should be carefully watched, studied, discouraged and prevented.

There is no doubt that the great majority of medical men, especially those who are willing to submit to regulation by organized American medicine, are ethical and wish to have nothing to do with merchandising. There are many sides to this complicated problem and many points of view which must be respected until we know every angle of the situation which has caused ophthalmologists to take a certain stand.

If all ophthalmologists and optometrists could and would free themselves from the personal dispensing of glasses, ethical standards would be raised.

This is too complex and important a subject to be discussed fully in the time at my disposal and requires study by a special committee with adequate funds to make a comprehensive investigation.

RESEARCH AND STUDY

Fortunately for the advancement of science, there are many young ophthalmologists who are interested in the broader concept of medicine. They should be associated with a clinic where they may be broadened by contact with other physicians. They should be interested in teaching and research and should stimulate others in investigative work. Some of the best and most important research may be done in the clinic.⁴

Office records should be complete so that they may be valuable for research. The young ophthalmologist should be constantly thinking of how he can improve his technic of examination and his instruments. He should attempt to make treatment less empirical. This is a form of research any one can do. Qualified men or those who can work under the supervision of competent ophthalmologists should endeavor to contribute to the knowledge of the many unsolved problems in ophthalmology, for example the etiology of chronic uveitis, cataract and glaucoma. Several foundations may be approached, if the problem to be studied is well presented and seems to offer the possibility of advancing science. The John and Mary R. Markle Foundation.

Snyder Ophthalmic Foundation, the Ophthalmological Foundation, the Josiah Macy Jr. Foundation and several others have contributed funds for research in ophthalmology.

Ophthalmologists should contribute to the literature and keep well informed concerning the writings and the technics of other surgeons and read current medical journals, not only the ophthalmic publications but also those in fields related to ophthalmology, e. g. embryology, physiology, bacteriology, immunology, pathology and, of course, psychiatry, medicine, general surgery and neurology.

ATTENDANCE AT MEDICAL MEETINGS AND PARTICIPATION IN LOCAL OPHTHALMIC ACTIVITIES

The young ophthalmologist should attend local eye meetings and conferences. In addition to attending local meetings of ophthalmologists he should become a member of the Association for Research in Ophthalmology. This association has been developed with the younger men in the profession in mind. The dues have been kept low, well within the financial range of the younger man who may not be able to afford the membership fee of the more expensive special medical societies. The association affords an opportunity not only to attend medical meetings but also to present the results of individual research. Certainly the younger men should have the opportunity of this form of stimulation and contact, and the holding of these meetings the day before the meeting of the Section on Ophthalmology of the American Medical Association stimulates interest in the section papers and exhibits. Derby⁵ and Feingold⁶ are former chairmen who in their presidential addresses stressed the value of attending medical meetings.

Every young ophthalmologist should join his county medical society and participate actively in the work, especially in these trying days for the world and medicine and the days to come, which can hardly be less difficult.

Every ophthalmologist should be interested in the prevention of blindness and should take an active part in the work of local societies as well as in the activities of the National Society for the Prevention of Blindness. They should interest themselves in the ophthalmologic public relations committees of the state and county medical societies, if they have been organized, or help to organize them, so that they can improve the standards of ophthalmology.

The mere existence of ethical standards cannot raise the standards of the practice of ophthalmology. The problem is more fundamental, and it is my belief that more attention should be given to selecting men for medical and ophthalmologic training because of their excellent character in addition to scientific or scholastic proficiency.

CONCLUSIONS

Because of changed conditions resulting from the war and awakened social consciousness, ophthalmologists have an important part to play in furnishing better medical service to low income groups. The needs and hopes of the free people in the world must and will be met. We may look to medicine to continue to provide unselfish leadership, scientific study and intelligent planning.

not be sustained but will diminish over a period of several hours as excess plasma protein leaves the blood stream. This is shown by changes in hemoglobin concentration in chart 1.

The advantages of albumin for use in shock and certain forms are chiefly those of safety and of its stability; it can be transported and kept for long periods without refrigeration, while it occupies but little space. It is ready for instant injection without reconstitution, cross matching or other preliminary testing. Its safety has been borne out by experience—and with the type of control used in its production and testing, reactions are almost unknown in clinical use. Its compactness is of great assistance in administering protein to children or to patients with poor veins. Thus, when it becomes available, albumin should be a very valuable addition to the emergency kit carried by the practitioner or kept in the accident room of a busy hospital.

Albumin is indicated in the treatment of conditions in which its high colloid osmotic pressure will be advan-

ments indicate that each gram of albumin should hold the equivalent of 18 cc. of fluid in the circulation and a 5.6 per cent albumin solution should be isotonic with a 7 per cent plasma.¹³ Thus 25 Gm. of albumin is osmotically equivalent to 450 cc. of circulating plasma

Chart 1—Contrast in the plasma volume change (as measured by the percentage change in hemoglobin concentration) after the injection of concentrated human serum albumin in a group of patients whose blood volumes had been depleted by acute hemorrhage and in a group with normal blood volumes. Note that immediate rapid hemodilution occurs in both groups (most normals received a smaller dose of albumin) but is sustained only in the group who had lost blood

tageous. At present we have data on its usefulness in two such groups of conditions—shock and hypoproteinemia.⁸

In shock, whether due to hemorrhage, trauma or burns, it restores the diminished blood volume toward normal by drawing on the extravascular fluids, and this is accompanied by clinical improvement. This has been demonstrated in dogs,¹⁰ in human volunteers who submitted to large venesections¹¹ and in clinical cases of shock.¹² The blood volume changes after treatment with concentrated human albumin in a group of 14 patients with shock due to trauma, hemorrhage and burns are shown in chart 2. Osmotic pressure measure-

or 500 cc. of citrated plasma. That these theoretical considerations are well substantiated by actual clinical experience is shown in table 2. For this reason the standard Army and Navy package contains 25 Gm., which is equivalent to the standard Army and Navy package of dried human plasma (500 cc.) but is only

protein to normal without harm to the patient, but unless the salt and water necessary to make up the deficit of fluid in both plasma and extracellular fluid are administered, the therapeutic effect will obviously be inadequate. This has been our experience in only a few cases of shock in civilian hospitals, all of which were caused by serious intra-abdominal disease in which vomiting had depleted the body fluids. Work on dogs¹⁴ has borne this out.¹⁵ The additional fluid does not necessarily have to be given by vein but may be given orally, if tolerated, or by any other available route.

The absence of the globulin components of plasma has not affected the usefulness of albumin in our experience with 100 shock cases, with 1 exception, a patient with a 50 per cent burn, in whom continued replacement with 300 Gm. of albumin in eighteen hours led

to hypoglobulinemia, which was readily corrected with plasma.⁸ The place of albumin in the treatment of shock is particularly in its early phases, when the emergency demands prompt restoration of blood volume, and in those cases in which peripheral circulatory failure is related to hypoproteinemia with edema. In the treatment of burns, plasma should be used to replace the losses of whole plasma, although albumin will carry patients through the first twelve hours if necessary.

The usefulness of albumin in the treatment of hypoproteinemia and edema remains to be explored to a large extent.⁸ Although we have given albumin in 25 Gm. doses daily for long periods of time to a number of hypoproteinemic patients, we have had an opportunity in only a few patients to use large doses in a short time, which seem essential for most efficient correction of hypoalbuminemia. In a number of cases of burns which had developed a syndrome of hypoproteinemia, edema and failure of the peripheral circulation as a result of treatment with large amounts of saline solu-

Chart 3—Clinical course of a baby with severe hypoproteinemia, who was given concentrated human serum albumin 6.25 Gm. (25 cc.) per day for four days. On May 19 the baby had severe anasarca and ascites, while on May 24 only slight edema remained about the area of infection on the forehead and scalp.

tion the infusion of 50 Gm. of albumin led to dramatic improvement. Chart 3 shows the results of administration of 25 Gm. of albumin in four days to a baby with hypoproteinemia associated with weeping eczema of two weeks' duration. The rapid decline in weight was accompanied by diuresis and disappearance of the edema and ascites, which were presumably due to hypoalbuminemia and aggravated by the administration of sodium bicarbonate. Thorn¹⁶ has emphasized the possible usefulness of albumin in cases of renal insufficiency with hypoproteinemia to raise the colloid osmotic pressure, thus increasing blood volume and glomerular filtration, and to supply protein without increasing the load of nonprotein nitrogen for the kidney to clear.

In certain chronic types of hypoproteinemia, albumin administration will increase the concentration of serum albumin if sufficiently large amounts are given. When doses of only 25 Gm. daily are used, a great deal must be given and only a small portion can be accounted

for in the peripheral circulation. The remainder is presumably stored or utilized while sparing other proteins, since no increase in nonprotein nitrogen excretion was observed in 3 hypoproteinemic patients whose nitrogen balance was studied during albumin therapy. In several cases of cirrhosis of the liver it has been possible to raise the level of serum albumin and to reduce the serum globulin by doses of 25 Gm. daily. In these patients some general improvement was noted, but no conclusions could be drawn concerning the control of ascites. When albumin injections were discontinued, the serum albumin level fell again within a month or two.

In patients with the nephrotic syndrome the administration of albumin was promptly followed by an increased excretion of protein in the urine.¹⁷ In certain patients no improvement was noted; in 2 children, however, the administration of very large amounts (500 Gm. to a 16 month old child in twenty days; 560 Gm. to a boy of 8 in a month) coincided with diuresis and decided clinical improvement, although in other patients this did not occur. Since the results

Moderate or casual exposure...	106	97 (92%)	8 (7%)	1 (1%)

Comment

1. Dose 5 cc. in most cases.
2. Day of injection varied from 1 to 9 days after exposure, chiefly 4 to 6 days.
3. Attack rate in age group 10 to 14 as reported by previous workers varies from 60 per cent to 15.4 per cent. Most of our patients were over 16.
4. The low attack rate makes evaluation difficult, but the fact that mild measles was more common than average measles in each group, whereas measles is usually severe in adolescents and adults, indicates that the globulin has had an effect.

have been irregular, this problem requires much more careful study.

In the treatment of hypoproteinemia with large doses of albumin, the powerful osmotic effect of albumin must be borne in mind. The patient should be watched for signs of venous and pulmonary congestion, and observation of the hemoglobin or hematocrit should enable the physician to follow the trend of the plasma volume over short periods. We have been impressed with how well large doses of albumin are tolerated, perhaps because of the low viscosity, but we observed 1 seriously ill elderly patient in whom doses of from 75 to 125 Gm. per day (650 Gm. in six days) appeared to exceed the limits of compensation.

SUMMARY TO PART I

1. By the application of large scale methods of fractionation developed in the Department of Physical Chemistry of the Harvard Medical School to pooled human plasma from blood collected by the American Red Cross, concentrated human serum albumin, γ -globulin antibodies, isohemagglutinins, fibrin films and fibrin foam with thrombin have been made available for clinical use.

17. Luetscher, J. A., Jr.: The Effect of a Single Injection of Concentrated Human Serum Albumin on Circulating Proteins and Proteinuria in Nephrosis, *J. Clin. Investigation* 23: 365-371 (May) 1944. Janeway, Gibson, Woodruff, Heyl, Bailey and Newhouse.

2. Concentrated human serum albumin, as dispensed in the standard Army and Navy package, provides a compact, stable solution ready for immediate use in the emergency treatment of shock.

3. The use of albumin in cases of shock due to hemorrhage, trauma and burns results in an increase in blood volume, hemodilution and clinical improvement. The blood volume is increased in these conditions by approximately the amount to be expected from measurements of its osmotic pressure (18 cc. per gram of albumin).

TABLE 6.—Complications of Measles in Children Under 12 Receiving γ -Globulin

(1,165 injections; 306 cases of mild measles, 34 cases of average measles)

Age	Dose Cc./Lb.	Days from Exposure to Infection	Result	Complications
2 yrs.	.02	9	Severe measles	Staphylococcus aureus pneumonia and empyema with recovery
11 mos.	.025	6	Average measles	Mild encephalitis with recovery
2 yrs.*	.025	..	Average measles	Otitis media (simple)

* Child had reaction with chills, fever and edema of eyelids day after injection of globulin.

Summary

1,843 injections; 32 reactions in 31 patients. 1.7 per cent reactions; one half local and one half general, chiefly fever, with one anaphylactoid type of reaction.*

TABLE 8.—Results in Young Adults with 5 Cc. Dose of γ -Globulin (Stokes and Maris)

Group	No. Cases	No Measles	Mild Measles	Average Measles
Immunized.....	63	54 (86%)	10*	1 (1.5%)
Controls.....	42	20 (48%)	4†	18 (42%)

* Very mild measles in 8, questionable measles in 2 (catarrhal symptoms and fever, but no rash).

† These cases more severe than in immunized group.

4. In the presence of severe dehydration, albumin must be supplemented with fluids in order to obtain the maximum therapeutic effect.

5. Albumin is an extremely safe blood derivative and can be administered very rapidly without reaction even after periods of heating at temperatures of 50 C. for as long as one hundred days.

6. Albumin can be used to correct hypoproteinemia if sufficiently large amounts are used.

7. In the nephrotic syndrome the injection of albumin is followed by a definite increase in proteinuria but does not regularly result in a diuresis.

PART II. γ -GLOBULIN IN MEASLES¹⁸

Normal serum γ -globulin antibodies (human) concentrated (immune serum globulin) have been prepared as a plasma fractionation product from blood collected by the American Red Cross by the methods of Cohn, Oncley, Strong, Hughes and Armstrong.² About 60 per cent of the antibodies are recovered in fraction II and appear to be γ -globulins, which comprise 96 per cent or more of the protein of recent preparations. Robinson¹⁹ early suggested that this globulin fraction from pooled normal plasma might be effective in the prevention and modification of measles.

Chart 4.—Results in 837 satisfactory prophylactic injections of γ globulin, as influenced by the size of the dose in terms of body weight and by the interval between injection and first probable exposure.

Enders²⁰ has reported on the concentrations of the great variety of antibodies which have been detected in γ -globulin preparations (fraction II). In these prepa-

18. The studies reported in this section would not have been possible without the cooperation of a number of agencies and individuals. Much of the work in Boston in 1943 was carried on by Dr. Charles W. Ordman. Field tests of globulin preparations against measles in 1944 have been carried out with the assistance of the Commission on Measles and Mumps, Board for the Investigation and Control of Influenza and Other Epidemic Diseases in the Army, in Philadelphia and Baltimore under the direction of Dr. Joseph Stokes, Jr., Dr. Elizabeth P. Maris and Lieut. S. S. Gellis, M. C., A. U. S.; in New York City, through the Department of Health, by Dr. Maurice Greenberg, Dr. Samuel Grant and Dr. David D. Rutstein, in Washington, D. C., under Capt. L. R. Newhouse (MC), U. S. N., and Dr. Lewis K. Sweet; in Durham, N. C., under Dr. W. C. Davison, and in Boston and vicinity with the cooperation of the Massachusetts Department of Health, the Massachusetts Antitoxin and Vaccine Laboratory and the Health Officers of Arlington, Medford, Malden and Chelsea. We are indebted to the large number of physicians in Boston, New York, Philadelphia, Baltimore, Washington and Durham who have provided most of the reports on which this study is based; to Dr. William B. Berenberg and the house and resident staff of the Children's Hospital for their assistance in the control and distribution of globulin, and to Miss Virginia S. Poole, B.S., who has kept the records, tabulated the data and prepared the charts for this report.

19. Cohn, E. J.; Luetscher, J. A., Jr.; Oncley, J. L.; Armstrong, S. H., Jr., and Davis, B. D.: Preparation and Properties of Serum and Plasma Proteins. III. Size and Charge of Proteins Separating on Equilibrium Across Membranes with Ethanol-Water Mixtures of Controlled pH, Ionic Strength and Temperature, *J. Am. Chem. Soc.* **62**: 3396-3400, 1940, see footnote, p. 3398.

20. Enders, J. F.: Chemical, Clinical and Immunological Studies on the Products of Human Plasma Fractionation: X. The Concentrations of Certain Antibodies in Globulin Fractions Derived from Human Blood Plasma, *J. Clin. Investigation* **23**: 510-531 (July) 1944.

rations most antibodies are concentrated approximately 25-fold over the pooled plasma from which they are derived. Variations in antibody titers from one preparation to another are slight, since the initial pool consists of the plasma from 2,000 to 4,000 donors, and the variations which do occur presumably reflect variations in the antibody levels of the population from whom the blood was drawn.

Proof that fraction II is a safe and effective agent for the prevention and modification of measles was obtained in 1943 by Stokes, Maris and Gellis²¹ and confirmed by Ordman, Jennings and Janeway.²² It is now being produced under Navy contract for the Army and Navy, and it has been our concern this year to test each preparation produced for its effectiveness against measles. Final tests of the material as a prophylactic agent against measles were carried out in children under 12 who were intimately exposed to the disease in the home, since it is known that the attack rate under such conditions is very high.²³ All injections were given intramuscularly. Reports were sent to a central office at least three weeks after injection, where the results were tabulated and analyzed.

RESULTS.

1. Effectiveness of γ -Globulin.—

Table 3 presents the comparison of γ -globulin with other agents used in measles prophylaxis in unselected cases.^{23a} Table 4 gives the results of the measles testing program for the satisfactory cases (children under 12, intimate home exposure, adequate follow-up data, injection before the tenth day after exposure).

We have been particularly anxious to ascertain the effectiveness of globulin in adults, a difficult problem, since the attack rate is low in this age group. Table 5 gives the results in 212 exposed and supposedly susceptible adolescents and adults.

2. Complications.—The rationale for attempting to modify measles is based on two premises: first, that modified measles confers a lasting immunity and, second, that the modified disease is much less serious. Proof of the first premise cannot be obtained as yet, but evidence for the second is available. Since the fatalities and serious sequelae from measles are usually associated with the development of complications, it is important to learn whether complications are less frequent in modified measles. In table 6 are listed the complications observed in a group of 1,168 children fulfilling our criteria for a satisfactory test of the globulin. The outstanding finding is that the only 3 complica-

21 Stokes, J., Jr., Maris, E. P., and Gellis, S. S.: Id XI The Use of Concentrated Normal Human Serum γ Globulin in the Prophylaxis and Treatment of Measles, *J. Clin. Investigation* **23**: 531-541 (July) 1944.

22 Ordman, C. W., Jennings, C. G., Jr., and Janeway, C. A.: Id XII The Use of Concentrated Normal Human Serum γ Globulin for the Prevention and Attenuation of Measles, *J. Clin. Investigation* **23**: 541-550 (July) 1944.

23 Stillerman, M., and Thalhimer, W.: Attack Rate and Incubation Period of Measles, *Am. J. Dis. Child* **67**: 15-21 (Jun) 1944.

23a The figures for convalescent serum, normal adult serum and plasma extract in table 3 are from McKinnin, C. F.: The Prevention and Modification of Measles, *J. A. M. A.* **109**: 2034 (Dec. 18) 1937.

tions observed were in cases in which the attempt to modify the disease apparently failed, as typical measles developed.

3. *Reactions.*—Most physicians who have previously used placental extract for measles prophylaxis have remarked on the low incidence of reactions following

Chart 5.—Satisfactory modification of measles in a sibling intimately exposed to an older sister. The initial bout of fever in each patient may have been due to an intercurrent infection with short incubation period. The large dose of globulin given just before appearance of the rash in the older child appears to have had no effect. This has been our general experience, but Stokes, Maris and Gellis²⁴ feel that γ -globulin may be useful in the early treatment of measles. The rash in the modified case consisted of about 50 minute pink, maculopapular lesions and might have been readily overlooked.

the use of γ -globulin. The reactions reported in 1,843 intramuscular injections are presented in table 7.

4. *Dosage and Time of Injection.*—In the reports based on clinical trials in 1943, both groups of authors²⁴ came to essentially similar conclusions concerning dosage. With the large number of satisfactory reports accumulated in two seasons, it has been possible to confirm the validity of these recommendations concerning the proper dosage of γ -globulin. Study of charts 4 and 6 will show very clearly that, whereas the results in the first eight days after exposure are directly dependent on the dose of globulin (calculated on a weight basis), the interval between exposure and injection makes much less difference, although the number of cases of mild and average measles increases after the fifth day. In other words, if complete protection is desired, give 0.1 to 0.075 cc. per pound as early as possible; if modification is desired, use one fourth of this dose (0.025 to 0.02 cc. per pound) on the fourth or fifth day. The fifth day after exposure is the usual time of administration in the home, since it is the day on which the rash usually appears in the source case. These dosage recommendations will give at best only about 80 per cent satisfactory

results, since the susceptibility of the individual, as emphasized by Stokes, Maris and Gellis,²⁴ is an important variable. This is brought out by the exceptional cases in chart 4.

The proper dosage for adults is difficult to determine. Stokes and Maris²⁵ have had the opportunity to make a controlled study in a group of 107 presumably susceptible college students who were exposed to active cases of measles in several meetings. A dose of 5 cc. was given to 65 of the group and 42 were not immunized. The results are shown in table 8. This suggests that the dosage schedule worked out on a weight basis for children may be applicable to adults, since the average dose used in this group was 0.04 cc. per pound, one which would be expected to give results similar to those obtained.

5. *Mild Measles.*—The modified form of measles which results after a proper dose of γ -globulin does not differ from that previously described. Most cases are milder in all respects and briefer in duration than typical cases. Each of the cardinal symptoms—catarrh, fever, malaise and rash (including exanthem)—may occur alone or in conjunction with the others, and with varying degrees of severity. Since rash is usually accepted as an essential feature of the disease, it is hard to classify cases with fever, cough and coryza occurring twelve to fourteen days after exposure, but at least 14 such cases occurred in the group reported. Close observation of the patient is usually necessary between the ninth and twentieth days after exposure if mild measles is to be recognized, as the rash may be sparse and transitory, and the fever short lived and unaccompanied by prostration. Chart 5 illustrates satisfactory modification of measles after home exposure.

Chart 6.—Graphic summary of the data in chart 4. On the left is shown the relationship between the results and the size of the dose in patients injected within eight days of exposure. On the right is shown the relationship between the results and the time of injection regardless of the size of the dose.

6. *Duration of Immunity.*—It is probable that the duration of passive immunity depends to a considerable extent on the dose given. Evidence from last year's work indicates that a large dose (0.1 cc. per pound)

24. Stokes, Maris and Gellis,²⁴ Ordman, Jennings and Janeway²⁵

25. Stokes, J. Jr., and Maris, E. P.: Personal communication to the author

confers immunity for at least three weeks²² and that a 5 cc. dose in adolescents does not protect after six to eight weeks.

7. *Use of γ -Globulin in Institutions.*—Communicable diseases are a particular problem in institutions caring for children. The two diseases which cause the greatest difficulty in pediatric wards because of their contagiousness are measles and chickenpox. γ -globulin has proved extremely useful in controlling outbreaks of measles in pediatric wards. It has been given in thirty-five separate outbreaks to 350 susceptible children with the following results: not followed 95, no measles 241 (94.6 per cent), mild measles 13 (5 per cent), average measles 1 (0.4 per cent).

Unfortunately, a few limited trials in outbreaks of chickenpox suggest that it does not protect satisfactorily against this disease, at least in doses of 5 to 20 cc.

SUMMARY OF PART II

1. γ -globulin antibodies (fraction II of Cohn, Strong, Oncley, Hughes and Armstrong) contains most of the antibodies of pooled normal human plasma in 25-fold concentration over the original plasma.

2. γ -globulin antibodies is the safest and most effective agent available for the prevention and modification of measles by passive immunization.

3. For this purpose the injection should be given preferably on the fifth day after exposure. At this time a dose of 0.1 to 0.075 cc. per pound will completely protect most susceptible individuals, while one of 0.025 to 0.02 cc. per pound will result in mild measles in most cases.

4. The mild measles in patients receiving globulin is similar to that previously observed in patients immunized with convalescent serum or placental extract. Complications were noted in 3 out of 400 cases of measles in immunized children but occurred in patients in whom globulin failed to modify the disease.

5. Reactions were noted in only 1.7 per cent of 1,843 intramuscular injections. Half of these consisted of local soreness and most of the remainder of fever. Only one anaphylactoid reaction occurred, which was probably due to an idiosyncrasy.

6. γ -globulin is very effective in controlling the spread and severity of measles in pediatric wards but does not appear to be effective in the control of chickenpox.

CONCLUSIONS

1. Fractionation of pooled human plasma from blood collected by the American Red Cross has yielded a number of products which have important clinical applications, while others are in process of development. Two of these products are concentrated human serum albumin and γ -globulin antibodies, which are discussed in this paper.

2. Concentrated human serum albumin exerts its expected osmotic effect when injected into the blood stream and this may be utilized in the treatment of shock and hypoproteinemic edema. It is an extremely safe, convenient and effective blood derivative.

3. γ -globulin antibodies constitutes the safest and most effective agent available for the prophylaxis of measles.

CLINICAL USE OF PRODUCTS OF HUMAN PLASMA FRACTIONATION

III. THE USE OF PRODUCTS OF FIBRINOGEN AND THROMBIN IN SURGERY

FRANC D. INGRAHAM, M.D.

AND

ORVILLE T. BAILEY, M.D.

BOSTON

In the course of large scale fractionation of human blood plasma in the Department of Physical Chemistry at the Harvard Medical School¹ purified fractions of human fibrinogen and thrombin have become available in large amounts. From these proteins, several materials have been prepared for use in surgery; these materials have a wide variety of physical properties and differ greatly in the surgical uses for which they are adapted. Two products have thus far proved satisfactory in clinical and experimental trials and are now ready for distribution. One is fibrin foam, which is used with a solution of thrombin as an absorbable hemostatic agent. Another is fibrin film, which has been employed as a dural substitute and in the prevention of meningocerebral adhesions. To a less extent the solutions of fibrinogen and thrombin have been used directly in certain special locations, where they provide a physiologic adhesive material by virtue of the clot produced when they are mixed in situ.

FIBRIN FOAM WITH THROMBIN, AN ABSORBABLE HEMOSTATIC AGENT

The importance of hemostasis in surgery has been recognized as long as surgery itself has existed. Use of the ligature was known to Celsus, and his description of it was doubtless copied from still earlier sources. New techniques for hemostasis in recent times, such as the silver clip and electrocoagulation, have come chiefly from neurosurgical investigators and have gradually found their way into those operations of the general surgeon, where they save time or secure more accurate control of bleeding than do traditional methods. This course has again been followed in the studies of human fibrin foam with thrombin, which was first used to control bleeding in neurosurgical operations and now promises to have use in certain general surgical procedures.

The characteristics of fibrin foam and the range of properties which may be secured by changes in the conditions of manufacture have been described elsewhere.² The fibrin foam is prepared from human

Read before the Section on Pathology and Physiology at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 14, 1944.

From the Surgical Services of the Children's and the Peter Bent Brigham hospitals and from the Departments of Surgery and Pathology, Harvard Medical School.

This work has been carried out under contract recommended by the Committee on Medical Research, between the Office of Scientific Research and Development and Harvard University.

This paper is number 31 in the series "Studies on Plasma Proteins" from the Harvard Medical School, Boston, on products developed by the Department of Physical Chemistry from blood collected by the American Red Cross.

Immunological Studies
XXII. The Develop-

fibrinogen and thrombin and therefore is wholly composed of proteins native to human blood plasma. Its outstanding characteristics are that it rapidly controls bleeding from oozing surfaces and large veins and that it is absorbed with minimal tissue reaction when left in place at the end of an operation.

The fibrin foam has a honeycomb structure composed of fibrin with air spaces of various sizes (fig. 1).

When it is to be used as a hemostatic agent, three bottles are supplied (fig. 2). One of these contains sterile fibrin foam, another dried human thrombin and the third 30 cc. of sterile isotonic solution of sodium chloride. At the time of use the saline solution is added to the dry thrombin; solution takes place rapidly. Pieces of fibrin foam are soaked in the thrombin solution and are then ready for use in hemostasis. The fibrin foam, which is firm and somewhat brittle in the dry state, becomes rubbery and shrinks as fluid enters the air spaces.

Fig. 1.—The appearance of fibrin foam before it has been soaked in thrombin solution. Note the porous structure.

The value of fibrin foam with thrombin as a hemostatic agent is greatly enhanced by the fact that it can be left in place. Absorption is rapid and the tissue reaction excited by the presence of the material is minimal from the point of view of the histologist and negligible from the point of view of the clinician. Since the fibrin foam remains on the bleeding surface after hemostasis is complete, it entirely obviates the recurrence of hemorrhage, so troublesome when cotton materials are removed from bleeding points.

FIBRIN FOAM WITH THROMBIN IN NEUROSURGERY

The use of fibrin foam with thrombin has greatly facilitated a variety of neurosurgical procedures. The bleeding from oozing surfaces may be controlled in other ways, but the rapidity and completeness of hemostasis secured with fibrin foam materially shortens the duration of operations in which this agent is used. Moreover, fibrin foam with thrombin stops bleeding under certain circumstances in which other methods have been unsatisfactory.

For use in any neurosurgical operation the dry fibrin foam is cut up into pieces of various sizes for use in the different types of bleeding which may be expected in that particular procedure. As the operation gets under way, these are placed in the thrombin solution so as to be ready for instant use. If minute fragments are wanted for control of small bleeding points, the moist fibrin foam can be picked up with forceps and cut or pulled apart. At the time when bleeding is encountered, a piece of the fibrin foam is selected and held firmly in place with a cotton pledget, which takes up excess moisture. Suction is often useful when applied over the pledget. It will then be possible to remove the pledget without dislodging the fibrin foam. The fragment can be molded somewhat to conform to the shape of the surface and will retain the configuration after excess moisture has been removed. Should additional hemostatic material be required because of unforeseen circumstances in the course of the operation,

dry fibrin foam will be suitable for use after soaking in the thrombin solution for one minute.³

When dealing with blood vessel malformations or surfaces with bleeding from numerous small vessels, it is of advantage to slice the fibrin foam so that it forms a wafer thin plaque. The fibrin foam will not smear but retains the form into which it is pressed. Bleeding from spurting arteries is controlled with silver clips or ligatures. While fibrin foam is not recommended for brisk arterial bleeding, it will occasionally be satisfactory if applied with sufficient pressure. Fibrin foam with thrombin is also not recommended for the scalp, the cut edge of the dura or the cut edge of the bone. It is, however, of great value in dealing with bleeding from the dural sinuses and the large veins entering them. When pieces of fibrin foam are placed against torn dural sinuses or large tributary veins, control of bleeding is more effective than that secured by the use of muscle.

One of the situations in which fibrin foam has been found most useful is the outer surface of the dura beneath the margins of the bone flap. Here bleeding is often troublesome and its control may occupy considerable time. The fibrin foam can be tucked beyond the limits of the wound with safety and left in place.

Again, fibrin foam is extremely valuable in dealing with bleeding from the beds of cerebral neoplasms. By its use, certain large tumors can be removed when otherwise it might not be safe to resect them completely or to take them out en bloc when they would have to be dealt with piecemeal without this hemostatic agent. When a tumor of this sort is to be excavated or removed in toto, preparation is made by securing a large mass of fibrin foam, usually large enough to fill the entire cavity. If the cavity is larger than the largest piece of fibrin foam available, several smaller

Fig. 2.—The package now in use for distribution of fibrin foam and thrombin. The center bottle contains dry fibrin foam. The right bottle contains dry thrombin and the left bottle isotonic solution of sodium chloride.

fragments may be pressed together. While the pieces of fibrin foam do not fuse, they adhere to one another well enough to make a compact ball. The application

3. Bailey, O. T., and Ingraham, F. D.: Chemical, Clinical and Immunological Studies on the Products of Human Plasma Fractionation. XXI. The Use of Fibrin Foam as a Hemostatic Agent in Neurosurgery; Clinical and Pathological Studies. *J. Clin. Investigation* 23: 591-596, 1944. Ingraham, F. D., and Bailey, O. T.: The Use of Products Prepared from Human Fibrinogen and Human Thrombin in Neurosurgery: Fibrin Foams as Hemostatic Agents; Fibrin Films in Repair of Dural Defects and in Prevention of Meningocerebral Adhesions. *J. Neurosurg.* 1: 23-39, 1944.

of several small bits of fibrin foam to a bleeding tumor bed would allow too much blood to accumulate among them. When the mass of fibrin foam has been pressed against the tumor bed, its volume is reduced by excavating the center. A relatively thin but continuous coating of fibrin foam is thus left along the tumor bed.

We have now used fibrin foam with thrombin as a hemostatic agent in 169 neurosurgical operations. From this experience it appears to be a most valuable hemostatic agent. Use of human fibrin foam with thrombin at successive operations on one patient is not attended by any untoward results. The fibrin foam does not replace the cotton pattie as sponging material but finds its use in the control of bleeding. A new absorbable hemostatic agent has thus been added to a very restricted group of these materials now in common use.

By far the most widely used of the absorbable hemostatic materials is muscle, introduced by Cushing in 1911.⁴ Fibrin foam with thrombin is superior in several important respects to muscle for this purpose.⁵ The tissue reaction to fibrin foam with thrombin is much less than that elicited by muscle, as discussed in another part of this paper. Furthermore, the surgeon who uses muscle must content himself with the limited supply which he may obtain from the temporal muscle or perform another procedure to obtain additional material from the gastrocnemius or other muscle or depend on the chance that muscle may be secured from a concomitant operation, which is not always possible. On the other hand, fibrin foam with thrombin is ready in any amount and can be placed on the instrument table with as little concern as is given to the provision of an adequate supply of instruments. Should an emergency arise as the operation progresses, an additional supply is available in a few moments.

Fibrin foam with thrombin can also be more readily adapted to the particular bleeding area than can muscle. The foam is broken or cut to size with ease and may be molded further to fit contours once it has been placed. The structure of muscle prevents this degree of adaptability. Both muscle and fibrin foam are entirely of human origin and share the advantages of homologous materials when used for human patients.

In general, muscle has been reserved for emergencies by neurosurgeons. When serious hemorrhage occurs, such as that from a dural sinus or blood vessel malformation, hemostasis is better controlled by means of fibrin foam with thrombin than with muscle, and the large amount which must be used makes the minimal tissue reaction to fibrin foam an important consideration. Fibrin foam with thrombin finds perhaps its largest field of use in situations where muscle would seldom be employed. A great deal of time may be saved by the use of fibrin foam with thrombin to control oozing on the dura, beneath the edge of the bone flap and elsewhere. This saving of time amounts to at least half an hour and often to an hour or more in a single operation. Fibrin foam with thrombin has saved the life of some patients in whom large tumors had been removed when muscle would have been unsatisfactory as a hemostatic agent.

Soluble cellulose has been prepared for use as a hemostatic agent when soaked in thrombin solution.⁶ After the demonstration by Frantz⁷ that soluble cellulose is rapidly absorbed with minimal tissue reaction, it was used with thrombin for hemostasis in neurosurgery by Putnam.⁸ Soluble cellulose and fibrin foam are both satisfactory from the standpoint of tissue reactions. While fibrin foam is made wholly from proteins of human origin, soluble cellulose is oxidized cotton. Our clinical experience with the two materials suggests that fibrin foam is superior to soluble cellulose as a hemostatic agent in neurosurgery. The control of bleeding by means of fibrin foam depends not only on the presence of thrombin but also on the way in which the thrombin is held in the honeycomb structure of the fibrin foam. Confirmation of this is seen in the fact that hemostasis is effected even when weak solutions of thrombin are used.² The loose structure of the soluble cellulose is less well adapted for the purpose and is not effective unless a considerably greater concentration of thrombin is available. Fibrin foam also has the advantage of being more easily cut and shaped to fit the individual characteristics of the bleeding point and especially of retaining the contours of the surface to which it is molded. From the standpoint of neurosurgery, the speed and tenacity with which fibrin foam adheres to tissues is very valuable. In our experience soluble cellulose has seemed less firmly adherent and the edges of the pledget have tended to curl away from the surface to which it has been applied.

Fibrin foam with thrombin has thus proved to be an effective absorbable hemostatic agent in many different types of neurosurgical operations.

TISSUE REACTION TO FIBRIN FOAM

It is of crucial importance that the tissue reactions caused by any absorbable material be minimal if its use is to be without danger in surgical procedures. Investigations of the tissue reactions to fibrin foam have been of two types—experimental studies, chiefly in monkeys, and studies of specimens removed at second operations or necropsies.³

Fibrin foam, as it comes in the bottle, appears microscopically to be composed of loose meshed fibers; these are actually cross sections of the honeycomb structure (fig. 3). When used as a hemostatic agent in conjunction with thrombin, the spaces fill with blood clot. This is followed by a shrinking and coalescence of the fibrin. The result is a minute mass of fibrin which persists for from one to four weeks (fig. 4). The absorption of the fibrin is accomplished by the intermediation of small numbers of mononuclear phagocytes and a few polymorphonuclear leukocytes. Giant cells occasionally form about the bits of fibrin. Fibrous tissue reaction is so slight that the location of the foam could usually not be identified in specimens obtained as late as one month after operation and often could not be located at much shorter intervals. These results are in conformity with the clinical observation that no untoward sequelae have been observed following the use of fibrin foam with

thrombin in 169 operations. The tissue reactions were not altered by the use of sulfadiazine or penicillin at the same time as the fibrin foam.

Because muscle has been successfully used for over thirty years as an absorbable hemostatic agent, it seemed worth while to compare the tissue reactions due to

Fig 3—The microscopic appearance of fibrin foam

muscle and those due to fibrin foam with thrombin. The experimental study of these two materials in the same monkey show conclusively that the tissue reaction to fibrin foam is very much less than that to muscle.⁶ A large mass of fibrin foam does not excite as much tissue response as one black silk suture or a bit of bone wax.

These studies indicate that the use of fibrin foam with thrombin as an absorbable hemostatic agent is safe from the standpoint of tissue reaction, even when large amounts are required.

FIBRIN FOAM WITH THROMBIN IN GENERAL SURGERY

After fibrin foam with thrombin had been given a thorough clinical trial in neurosurgery and shown to be safe by experimental and follow-up studies, possible applications in general surgery were considered. Preliminary experimentation in various sites was therefore carried out. This indicated that the tissue reactions in the liver, peritoneum, lung, kidney and abdominal wall were similar qualitatively and quantitatively to those already described in the tissues of the central nervous system. Again it appeared that large amounts of fibrin foam with thrombin were rapidly absorbed and produced so little fibrous tissue reaction that its site could be determined with difficulty or not at all when microscopic sections were studied a month or less after operation. The use of fibrin foam with thrombin as a hemostatic agent in many sites outside the nervous system was therefore considered a safe procedure.

In neurosurgery a small amount of ooze may make the difference between success of the operation and fatality. The same amount of hemorrhage in the operative fields of the general surgeon may lead to complications in wound healing but is seldom crucial in the survival of the patient. Fibrin foam with thrombin is not therefore necessary as a routine in these procedures.

There are, however, several circumstances in which large amounts of oozing occur in general surgery and in which ligature, endothermy and other conventional methods of hemostasis are inadequate. Experience with the use of fibrin foam with thrombin in these operations has as yet been limited, but the results to date indicate that it may be possible to control the hemorrhage satisfactorily with the new absorbable hemostatic agent.

One situation in which fibrin foam with thrombin has proved valuable is the cut surface of the liver. It was possible to stop the ooze from this site when it was exposed during the resection of a large carcinoma of the stomach with extension to the right lobe of the liver. Injuries to the liver might be treated in the same way. It appears that the best way to handle hemorrhage from the cut surface of the liver is to put silver clips on spurting arteries and to coat the surface with fibrin foam soaked in thrombin. The same hemostatic agent has proved of great value in controlling ooze of the gallbladder bed in cholecystectomy. While this bleeding is satisfactorily controlled by conventional methods, the completeness and rapidity of hemostasis secured by fibrin foam with thrombin facilitates the procedure considerably.

The material also controls very well the oozing in abdominal wounds when operations are performed on jaundiced patients. It is possible to cover the entire surface of the wound with this hemostatic agent, if necessary, without fear of untoward tissue reactions.

Fig. 4—The only residuum of the large mass of fibrin foam left on the surface of the dura seventeen days previously.

Persistent ooze not controlled by the usual methods of hemostasis occurs in occasional operations undertaken for a variety of conditions. Such bleeding has responded favorably to the application of fibrin foam and thrombin in seven gynecologic procedures, as well as in radical mastectomy and nephrotomy. While on a

priori grounds it would appear that fibrin foam with thrombin would be useful in many of the operations of thoracic surgery, experience thus far has been limited. One instance is of especial interest. In this case a mediastinal tumor was resected, leaving a slowly oozing bed. Application of fibrin foam with thrombin brought the bleeding promptly and completely under control.

Further clinical experience in the use of fibrin foam with thrombin as a hemostatic agent in general surgery is accumulating rapidly. Its effectiveness in a large variety of sites has been clearly demonstrated, and no contraindications to its use have thus far appeared.

FIBRIN FOAM WITH THROMBIN IN HEMOPHILIA

The prevention of hemorrhage in hemophilia has not yet been accomplished, despite numerous investigations in that direction. Surgeons faced with operations on patients suffering from that disease are confronted with a difficult problem in deciding whether it is more dangerous to forego operation or to chance the excessive bleeding which will inevitably result. This perhaps comes up more often with tooth extractions than in any other single type of procedure. When teeth are removed from patients with hemophilia, bleeding may continue for days or weeks despite packing and transfusions. It has been shown⁹ that rabbit thrombin controls such bleeding satisfactorily. Fibrin foam with thrombin has also proved to control the bleeding from the tooth sockets of patients with hemophilia quickly and completely, even when careful packing and repeated transfusions have proved ineffective.

There is considerable oozing from the tooth sockets of patients who do not have hemophilia. The packing of these tooth sockets with fibrin foam soaked in thrombin has proved of considerable value even though the serious results encountered in hemophilia were not anticipated.

Other operations in which fibrin foam and thrombin has been used to control the bleeding in hemophilic patients has been limited to the repair of a laceration of the tongue and another of the lower extremity. In each of these instances, hemostasis was prompt and complete.

SOLUTIONS OF FIBRINOGEN AND THROMBIN IN SURGERY

There are certain conditions in which it has been found advantageous to use fibrinogen and thrombin solutions rather than products manufactured from them. Cronkite, Lozner and Deaver¹⁰ have published an account of the use of these solutions in skin grafting. Experience in this clinic also indicates that these solutions are of considerable value in affixing skin grafts to the recipient sites. The grafts are placed in a solution of thrombin and the recipient site is painted with a solution of fibrinogen. When the thrombin soaked graft is laid on the prepared recipient site, a clot is rapidly formed. This acts as a glue which holds the graft in place and allows satisfactory taking.

Solutions of thrombin have also been used in otolaryngologic procedures. They are effective in controlling nasal hemorrhages in patients with leukemia as well as in those without blood diseases. The solutions may be painted or sprayed on the surface or applied by packing the nose with cotton soaked in thrombin. Solutions of thrombin are also of considerable value in securing hemostasis during tonsillectomy. While it

would be advantageous from certain points of view to use fibrin foam soaked in thrombin under these circumstances, the possibility of aspiration of bits of foam makes one hesitate to employ it except for patients who are fully conscious and have an active gag reflex or for patients under general anesthesia who are very carefully watched.

With the exception of such special situations as those discussed, hemostasis is better secured by the use of a matrix to hold the thrombin solution than it is by the solution of thrombin alone.

FIBRIN FILM IN SURGERY

It has been possible to prepare a film from solutions of fibrinogen and thrombin which are allowed to clot under conditions entirely different from those used in preparing fibrin foams.¹¹ The film is translucent, somewhat elastic and pliable. It presents physical properties which meet the requirements for a dural substitute. Experimental investigation of the use of fibrin film as a dural substitute was carried out on a series of monkeys.¹² These experiments indicated that the film was slowly replaced by fibrous tissue without the formation of meningocerebral adhesions. It thus proved a satisfactory substitute for dura under experimental conditions. The tissue reactions were not altered by the simultaneous use of sulfadiazine or penicillin.

We have used fibrin film in the repair of dura and in the prevention of meningocerebral adhesions in 59 cases. The use of the fibrin film under these circumstances has proved to be highly successful and no evidence of untoward sequelae have appeared, even though some of the patients have been followed as long as one year.

In the evaluation of a new substance for use as a dural substitute, great caution must be exercised because of the possibility of the late appearance of unfavorable reactions to its presence. In our experience so far, fibrin film has proved more satisfactory than any other material tested as a dural substitute. In addition to its safety, fibrin film is well adapted for use in the repair of dural defects because of its translucence, flexibility, ease of handling and adaptability to any contour.

It is possible that there may be applications of fibrin film to problems in general surgery. To this end, experiments have been begun to test the tissue reactions of fibrin films in joints, in the eye, in the peritoneum, about nerves and elsewhere. These applications of fibrin film are at present in the experimental stage, and the use of the material except as a dural substitute is not recommended at this time. The possibility of unfavorable reaction to fibrin film in general surgery must be borne in mind and each site thoroughly investigated experimentally before it is used in the clinic.

SUMMARY

The preparation of purified human fibrinogen and thrombin has made possible new materials for use in surgery. The solutions of the proteins may be employed and a variety of products prepared by combining them under different conditions.

Of these, fibrin foam with thrombin is a new absorbable hemostatic agent prepared from fibrinogen and thrombin of human blood plasma.

Bailey and Ingraham.

Extensive clinical use of fibrin foam with thrombin in neurosurgical operations has shown it to control oozing from the dura, from beneath bone flaps and from the cerebral tissues as well as from the dural sinuses and large veins. It is not recommended for brisk arterial hemorrhage.

The tissue reaction to fibrin foam with thrombin is minimal and negligible from the clinical standpoint. In this respect, as well as in availability, ease of manipulation and adaptability, it is much superior to muscle. Fibrin foam with thrombin is prepared wholly from materials of human origin.

This hemostatic agent can be used with advantage in certain procedures by the general surgeon. It is also effective in controlling hemorrhage in patients with hemophilia.

A limited use has been made of solutions of fibrinogen and thrombin in certain special situations in which it is desirable to form a clot *in situ*.

Fibrin film is a homogeneous sheet prepared from human fibrinogen and thrombin. It has proved effective in the repair of dural defects and in the prevention of meningocerebral adhesions.

ABSTRACT OF DISCUSSION

ON PAPERS OF DR. JANEWAY AND DRS.
INGRAHAM AND BAILEY

DR. ORVILLE T. BAILEY, Boston: There has been an inclination, because of the nature of most investigations on purified proteins, to regard them as unstable substances, but the preparations of albumin may be frozen, thawed and injected clinically without causing reactions. They may be kept at tropical temperatures for periods of many months, and severe shaking does not change them in such a way that they cause reactions in patients when injected subsequently. A number of hospitals have sent the tissues of patients receiving large amounts of albumin to learn whether there are any pathologic effects which may be due to the presence of the administration of such an unusual amount of one fraction of human plasma. Pathologic changes which could be correlated with the injection of the albumin could not be found. Since fibrin foam, to be effective, must be left in place, it should elicit a minimal tissue reaction and this is found to be the case. Fibrin foam, when it is fixed directly, consists of cross sections of the honeycombs of which it is composed. When it has been left on the surface of the dura for fourteen hours the meshes of the honeycomb have become filled with blood clot. There is practically no cellular infiltration in response to its presence. At the end of twenty-four days a large mass of fibrin foam has become reduced to a small structure, filling only a high power field, and is surrounded by a minimal amount of connective tissue. It is difficult to make sure that even this small amount of connective tissue is due wholly to the presence of the fibrin foam, because the blood clot which the fibrin foam is left in place to produce will usually result in the production of more fibrous tissue than that. Experiments were set up in monkeys to compare the tissue reaction of muscle and fibrin foam as hemostatic agents. The material was introduced into the cerebral cortex. At the end of four weeks there is practically no reaction to the presence of the fibrin foam. It has become somewhat coalesced and is nearly absorbed. When a piece of muscle of similar size is left in a comparable place on the opposite side of the same animal there is considerable gliosis about the fragment, and the muscle is being converted into a mass of richly collagenous connective tissue. Some of the blood vessels which were present in the original fragment of the muscle are still present. This indicates that the reaction to fibrin foam is many times less than it is to muscle, and this permits us to use fibrin foam in a great many situations where we might fear tissue reaction from muscle.

A STUDY OF "PENICILLIN FAILURES"

ARTHUR L. BLOOMFIELD, M.D.

WILLIAM M. M. KIRBY, M.D. .

AND

CHARLES D. ARMSTRONG, M.D.

SAN FRANCISCO

In studying a new therapeutic agent it is necessary not only to discover the conditions in which it is effective but also to define the circumstances under which it fails or at least yields unsatisfactory results. Penicillin has now been used long enough to make possible the compilation of lists of those infections in which it seems to be of value.¹ But such bare enumerations do not begin to tell the story, as there are all sorts of special circumstances which arise in the individual case to modify any general statement. From an intensive study of over 100 patients treated with penicillin a good deal has been learned about what might be called "penicillin failures"; it is with this phase of the subject that the present paper is concerned.

"Penicillin failures" may be discussed under the following headings:

1. Causes of death in penicillin treated patients.
2. Failures due to inadequate amounts of penicillin.
3. Failures due to inadequate surgical drainage in penicillin treated cases.
4. Failures due to overwhelming infection even when penicillin dosage was presumably adequate.
5. Failure to prevent or cure renal lesions in penicillin treated cases of streptococcal infection.
6. Conditions in which penicillin either fails or is likely to be inadequate.

1. CAUSES OF DEATH IN PENICILLIN TREATED CASES

Aside from patients who were not seriously ill, such as those with primary syphilis, mild sulfonamide fast gonorrhea or furunculosis, we have treated 87 instances of severe infection including endocarditis, meningitis and acute osteomyelitis. An idea of the general character of the material is obtained from the fact that 27, or 31 per cent, of these patients had bacteremia. Of this series of 87 patients 7, or 8 per cent, died. An analysis of these fatal cases is given in the accompanying table. It appears that only 2 deaths (cases 6 and 7), or 2.3 per cent of the whole series, could be ascribed to actual failure of penicillin treatment. Ten years ago one would have had a mortality of at least 50 per cent.

2. FAILURES DUE TO INSUFFICIENT PENICILLIN THERAPY

It is not our present purpose to discuss the unsettled question of adequate penicillin dosage. Excellent results have been reported with relatively small quantities of the material,² but this does not rule out the need of larger doses in some cases. At any rate the unsatisfactory results in the following patients seemed to be ascribable to too small amounts of penicillin or to treatment of too brief duration.

From the Department of Medicine, Stanford University School of Medicine.

The Penicillin was provided by the Office of Scientific Research and Development from supplies assigned by the Committee on Medical Research for clinical investigations recommended by the Committee on Chemotherapeutics and Other Agents of the National Research Council.

2. Herrell, W. E.: The Clinical Use of Penicillin, an Antibacterial Agent of Biologic Origin, *J. A. M. A.* 124: 622 (March 4) 1944.

The following case concerns relapse of an infection which probably could have been prevented by more prolonged treatment of the original attack, although the daily dose seemed adequate:

CASE 8—A woman aged 61 entered the hospital on the fifth day of a typical facial erysipelas. The eruption extended over the nose to the malar prominences and ordinarily would have continued to spread for several days. She was given an intravenous dose of 35,000 units of penicillin and thereafter

seems clear that with any serious infection it may be well to continue treatment for several days after the process has been controlled as possible insurance against recurrence. This applies especially to staphylococcal and streptococcal infections. In *Streptococcus viridans* subacute bacterial endocarditis the good results which we have obtained in a consecutive series of 9 cases seems due to the continuation of uninterrupted treatment over a period of six to eight weeks. Recurrences of acute

Patients Who Died Under Penicillin Treatment

Case	Clinical Diagnosis	Treatment	Anatomic Diagnosis	Comment
1	Lung abscess following aspiration of potato chip, 4 week's duration; high fever; abscess at least 15 cm in diameter; huge amount of foul sputum containing various streptococci and putrefactive anaerobes; a desperately ill patient with progressive gangrene of lung, with diabetes of moderate severity	Penicillin by continuous intravenous drip, 300,000 units per day; after 3 days with condition generally better she died suddenly in acute collapse	A huge lung abscess occupying practically the entire right upper lobe was found; there was no evidence of air embolus, no pulmonary embolus, no edema of lungs; in short, no anatomic cause of death was found	Contents of abscess obtained at autopsy showed no growth on culture, so that the penicillin had been effective to some extent, treatment had not gone on long enough before she died to draw any further conclusions as to efficacy; no cause for sudden death was found; the lots of penicillin used in this case gave no reactions in other patients, and penicillin clearly had nothing to do with her death
2	A patient in the last stages of lymphoid leukemia developed acute lobar pneumonia of left lung with 150 colonies per cubic centimeter of type 1 pneumococcus	Treatment started on fifth day of disease, 200,000 to 300,000 units by continuous intravenous drip; rapid improvement and 12 days later when apparently convalescent went into collapse with high fever and died in 24 hours	The pneumonia on the left was practically resolved; there was a fresh consolidation of the right middle lobe, which showed no pneumococci but an unidentified bacillus; extensive lesions of leukemia	A dying leukemic woman with terminal type 1 pneumococcal sepsis with heavy bacteremia and lung consolidation was cleared of her pneumococcal infection but died of leukemia and another different (bacillary) infection
3	A young man with a fistula from esophagus to lung and huge paravertebral abscesses from which nonhemolytic streptococci (sensitive to penicillin) were grown; no tubercle bacilli found on extensive search of pus and sputum	Intensive intravenous, intramuscular and local penicillin therapy for about a month	Huge tuberculous paravertebral abscesses; tubercle bacilli easily demonstrated in scrapings from granulation tissue	A misdiagnosis. This patient would not have been treated had the correct diagnosis of tuberculosis been made
4	A man aged 46 had pneumococcal sepsis with 25 to 50 colonies of type 25 pneumococcus per cubic centimeter of blood; there were evidences of endocarditis, arthritis and meningitis	Intensive treatment of up to 400,000 units daily by intravenous drip, also intrathecal penicillin; treatment over a period of 3 weeks eliminated all evidence of pneumococcal infection (sterile blood and spinal fluid cultures) but he developed a huge bed sore with general failure and died	No autopsy.....	There was every evidence here that the pneumococcal sepsis was cured; death was clearly due to infection from a huge bed sore and perhaps could have been avoided
5	A woman aged 22 was desperately ill with a gas bacillus infection following attempted abortion (Clostridium welchii grown from cervical discharge)	After 5 days of intensive penicillin therapy by intravenous drip the gas bacillus infection was entirely cleared; she was oliguric on entry and went on to uremia and anuria of obscure origin—possibly associated with transfusion or sulfonamides received before entry	All evidences of uterine infection cleared up; kidneys showed a peculiar diffuse lesion—still under study	C. welchii infection cleared under penicillin, but she died of renal disease which was already under way when treatment was started
6	A woman aged 39 with old rheumatic mitral disease infected her finger by pin prick and developed Staph aureus bacteremia, 800 colonies per cubic centimeter; she seemed moribund with jaundice, high fever and anemia; the staphylococcus was highly sensitive to penicillin in test tube	Given penicillin by intravenous drip at rate of 300,000 units in first 20 hours; at this time blood culture (with penicillinase) still positive—130 colonies per cubic centimeter—no growth without penicillinase, indicating a high blood level; progressive cyanosis and dyspnea; death 24 hours after entry	Old mitral lesion with fresh acute ulcerative endocarditis; no special cause of death found	This case must be considered a penicillin failure; in spite of intensive treatment and high blood level, bacteremia was not controlled soon enough and she died in toxemia
7	A man aged 59 was in hospital for nearly 5 months with recurring S aureus sepsis	Received a total of 7,500,000 units of penicillin	Subacute pericarditis, subacute meningitis, small abscesses in kidney	This case also must be set down as penicillin failure, although it is now believed that his treatment was inadequate in amount

15,000 units intramuscularly every three hours. There was no further spread of the process, and within twenty-four hours it seemed to have completely subsided. The temperature dropped promptly (fig. 1) and penicillin was continued for only two days—a total of 255,000 units. Three days later she left the hospital apparently well but after an interval of seven days returned again with typical facial erysipelas. This was clearly a second attack and not a residue of the first. Penicillin was given once more with prompt arrest of the erysipelas, but this time treatment was continued for nine days—a total of 1,180,000 units (fig. 1).

There is every reason to believe that the second attack would not have occurred had treatment been continued for a longer time after the first bout. It

hemolytic streptococcus throat infections, common with brief treatment,³ can be prevented by giving penicillin over a period of five to ten days.

In the next case also the poor result may be due to the fact that treatment was stopped too soon:

CASE 9.—A school boy aged 8 years was admitted on the third day of an acute osteomyelitis of the left femur. The left thigh was hot, red, greatly swollen and acutely painful. There was high fever with leukocytosis, and a blood culture was positive for *S. aureus*. Penicillin was started on the following (fourth) day in doses of 150,000 units per day by continuous intravenous drip. Treatment was continued for only twelve days and was then stopped, although the temperature

3 Rantz, L. A.: Personal communication to the authors

had not yet reached normal (fig. 2). A roentgenogram on entry showed no visible lesion in the bone, but on the thirteenth day of the disease an early destructive process was detected by x-ray just proximal to the epiphyseal line of the lower femur. No periosteal reaction was seen at this time. The patient left the hospital on the twenty-fourth day of the disease

Fig. 1.—Graphic record of case 8

with normal temperature, no pain and only very slight swelling of the leg just above the left knee. Frequent roentgenograms from this time on showed progressive destruction and absorption of the lower two thirds of the femur and a pronounced periosteal reaction throughout its length. After three months there was obvious sequestration and finally a pathologic fracture. X-ray films made on the thirteenth day and at the height of the lesion several months later are shown in figures 3 and 4

Our experience in 8 cases of acute osteomyelitis of the long bones in which no operation was done indicates that very intensive and prolonged therapy is necessary if serious changes are to be prevented. Even then, as reported by others also, the x-rays from the second week on usually show some absorption of cortex with periosteal reaction possibly due to injury which began before penicillin therapy was started. Some staphylococci must be sealed in and difficult to reach in areas made relatively avascular by thrombosis and necrosis. It is possible, if not probable, that more prolonged therapy of patient 9 might have arrested the process at an earlier stage as it appears to have done

Fig. 2.—Graphic record of case 9

in our other cases. At any rate prolonged uninterrupted treatment is clearly indicated in acute osteomyelitis. This whole subject will be dealt with in detail in another paper.

In case 7 in the table it is our belief that death might have been prevented by more intensive and continuous therapy.

This man, with severe diabetes, developed *S. aureus* sepsis with positive blood culture following a skin injury. On entry there were skin lesions and osteomyelitis of the left humerus. Pericarditis was detected (friction rub) a few days later. He was one of our early cases and after ten days of penicillin (2,000,000 units) treatment was arbitrarily stopped. Over a period of five months there were repeated episodes of *S. aureus* infection of various structures with recurring positive blood culture, although the organism was always sensitive to penicillin in vitro. Treatment with penicillin, given during each exacerbation, in the end totaled 7,500,000 units but was never continued over a period of more than ten days at a time. The patient finally left the hospital feeling fairly well, with normal temperature and with no obvious foci, but on reaching home he again developed fever with left upper abdominal pain, failed rapidly and died in twelve days. At autopsy pertinent points were "subacute and chronic pericarditis, subacute and chronic myocarditis, subacute meningitis, small abscesses of kidney." There were also large infarcts of the spleen

Fig. 3—Left femur in case 9 on December 20, the thirteenth day of disease, showing early absorption and periostitis.

Fig. 4—Left femur in case 9 on April 4, showing advanced changes with sequestration and pathologic fracture.

This patient furnishes a typical example of penicillin therapy which during a long relapsing infection always fell short of the mark. It seems probable from experience in subsequent cases that intensive uninterrupted treatment over a period of four to six weeks would have cured this man. The hazard of too little and too brief therapy, which in our experience is especially great with staphylococcal infections, is illustrated.

3. FAILURES ASSOCIATED WITH PENICILLIN THERAPY WHEN ADEQUATE SURGICAL DRAINAGE OF INFECTIONS WAS NOT CARRIED OUT

In spite of the great efficacy of penicillin in controlling certain types of infection, the principle that evacuation of closed collections of pus is necessary for rapid cure still holds good in most cases.⁴ Simple

⁴ Keefer, C. S., and others. Penicillin in the Treatment of Infections, *J. A. M. A.* 122:1217 (Aug. 28) 1943.

aspiration of pneumococcal empyema⁵ and of gonococcal joints, with injection of penicillin, has, to be sure, been adequate in many cases, but with other infections, especially those due to staphylococci and nonhemolytic streptococci, progress may be arrested until surgical drainage has been instituted. The problem is illustrated by the following cases:

CASE 10.—A man aged 38 developed subphrenic abscesses probably following perforation of a viscus. The abscesses were incised and drained and an anaerobic nonhemolytic streptococ-

Fig. 5.—Graphic record of case 10.

cus, highly sensitive to penicillin, was isolated. He received intensive penicillin therapy (2,290,000 units) by continuous intravenous drip, as well as locally, for eleven days. His temperature gradually fell almost to normal and he seemed much better, but fever recurred with leukocytosis and abdominal pain. It was evident that there was more pus, and drainage of an encapsulated pocket was done through the previous incision. Penicillin (1,515,000 units) was given intramuscularly over a period of eleven days and the temperature again fell to normal with clinical improvement. He was not entirely well, however, and fever soon returned. This time x-rays showed a lung abscess which appeared to have developed under penicillin therapy. The same organism obtained from the subphrenic abscess was grown from the lung lesion, which was drained surgically. Another intramuscular course of 1,000,000 units was given with injection of 26,000 units into the abscess cavity. There was now rapid healing of all lesions, and the patient was discharged well after a hospital stay of three months and a total of 7,400,00 units of penicillin. Figure 5 shows the portions of the course before and after drainage of the lung abscess. One sees that in spite of intensive penicillin the temperature did not drop until drainage was instituted.

The streptococcus in this case was highly sensitive to penicillin in vitro, but the whole situation is difficult to evaluate. Those who saw him felt that he did better than patients of this sort usually do with surgery alone. On the other hand there were two relapses in spite of intensive penicillin treatment, each associated with an undrained collection of pus.

The following case is even more clearcut:

CASE 11.—A man aged 66 was brought to the hospital with the story of sudden onset of sharp pain in the right side of the chest two weeks previously. This had continued with fever, prostration and general failure. There had not been cough, sputum or any suggestion of bronchitis or pneumonia. On entry he looked ill and had sweats and fever. There were signs of fluid in the right chest and, on tapping, thin yellow purulent fluid was obtained. It had an extremely foul odor. Smears showed innumerable bacteria and on culture nonhemolytic streptococci and an unidentified gram positive bacillus were grown. Between April 13 and April 29 the chest was aspirated seven times, and on five occasions penicillin was injected into the pleural cavity in amounts of 50,000 to 100,000 units, a total of 495,000 units. There was considerable improve-

ment under this program, and by the 29th the fluid was no longer foul and no organisms were seen or grown. However, 50 cc. of yellow thickish pus was obtained and the patient continued to feel ill and to have a variable fever with leukocytosis. On April 27 (fig. 6) penicillin was started intramuscularly at the rate of 120,000 units daily in eight doses, but after five days there was no improvement so that operation was finally done, a tube inserted into the pleura and tidal drainage instituted. The temperature promptly fell to normal. The patient recovered rapidly and left the hospital well on May 20.

In this case thoracentesis with local injection of penicillin led to partial control of the infection and did away with the foul nature of the pus. However, no complete clearing could be obtained until a tube was inserted for continuous tidal drainage. This has been our general experience in other instances of streptococcal and staphylococcal empyema.

4. FAILURES DUE TO OVERWHELMING INFECTION

Patient 6 in the table is the only example we have had of failure of penicillin due simply to an overwhelming infection with an organism sensitive in vitro. She received large doses of penicillin by continuous intravenous drip, sufficient to raise the blood content to well over the standard bacteriostatic level of 0.15 unit per cubic centimeter.⁶ In spite of this the blood stream was not cleared and after twenty hours culture still yielded 130 colonies of *S. aureus* per cubic centimeter. The importance of using penicillinase⁷ is also brought out, as there was enough penicillin in the blood to inhibit growth in a blood culture made without penicillinase.

5. FAILURE TO PREVENT OR CURE THE DEVELOPMENT OF GLOMERULAR NEPHRITIS IN CERTAIN PATIENTS WITH STREPTOCOCCIC INFECTIONS TREATED WITH PENICILLIN

The association of glomerulonephritis with certain types of streptococcal infection is clearly established. When penicillin became available it seemed of particular importance to find out if this agent, which extirpates so many streptococcal infections with great speed, would prevent the occurrence of nephritis. Of no less interest was the question of whether nephritis

Fig. 6.—Graphic record of case 11.

already established would clear up after elimination of concomitant streptococcal infection by penicillin, as for example in bacterial endocarditis.

CASE 12.—A man aged 66, some time after a burn of the left shoulder, was brought to another hospital because of high fever, shortness of breath and swelling of the left leg. Blood culture was found positive for hemolytic streptococci but in spite of intensive sulfadiazine therapy and two transfusions

5. Tillett, W. S.; Camber, M. J., and McCormack, J. E.: The Treatment of Lobar Pneumonia and Pneumococcal Empyema with Penicillin, *Bull. New York Acad. Med.* 20: 142, 1944.

he had gone steadily downhill. On entry to Stanford Hospital (fig. 7) he seemed desperately ill. The temperature was 40.5 C. (104.9 F.). The remains of a small burn on the right shoulder were visible but the lesion was almost healed. There were many petechiae, a faint systolic murmur at the apex and soft edema of both ankles, but the left leg was much more swollen than the right. Blood culture yielded 400 colonies per cubic centimeter of hemolytic streptococci. He was moderately anemic and the blood urea was 90 mg. per hundred cubic centimeters. The urine contained considerable protein, immense numbers of red cells, white cells and casts of all sorts. The

Fig. 7.—Graphic record of case 12.

diagnosis was sepsis, hemolytic streptococcus, with bacteremia, phlebitis of the left femoral vein, and acute glomerular nephritis associated with the streptococcal infection. Penicillin was given by continuous intravenous drip at the rate of 300,000 units per day, and within twenty-four hours the blood culture showed no growth and the temperature fell abruptly to normal. On the fifth day there was an unexplained rise of temperature, which may have been due to a small pulmonary embolus. Penicillin was stopped on the ninth day with the temperature normal and the patient much improved, but the urine was essentially unchanged and the blood urea was still 78 mg. per hundred cubic centimeters. Two days after penicillin was stopped he had a chill with rise of temperature to 40 C. (104 F.) and blood culture was again positive, showing 5 colonies of hemolytic streptococci per cubic centimeter. Penicillin was given again, intramuscularly, for three weeks. The temperature fell promptly to normal and never rose again above 37.5 C. (99.5 F.) nor was the blood culture again positive.

In spite of the elimination of the streptococcal infection the nephritis seemed unaffected. The urine continued to show protein, large numbers of red cells and casts. The blood urea rose as high as 235 mg. per hundred cubic centimeters. Soft edema continued. His general condition gradually improved, so that by May 1944, four months after leaving the hospital, he felt very well and the blood urea was only 40 mg. per hundred cubic centimeters. The blood pressure was 150/85. Except for slight pitting, edema had disappeared. The urine, however, showed the typical findings of a glomerular nephritis in the subacute stage. An Addis count gave protein 0.35 Gm. in twenty-four hours, red blood cells 250 million in twenty-four hours, white and epithelial cells 55 million in twenty-four hours and casts 500,000 (granular, hyaline and a few blood casts). This case also illustrates relapse of an acute infection with recurrence of positive blood culture when penicillin was stopped too soon.

There is every reason to believe that this patient's streptococcal infection was completely eliminated. There is no evidence, however, that the course of the nephritis was influenced and every reason to believe that an irreversible lesion has been set up which will progress in the usual relentless fashion of chronic glomerulonephritis.

Similar observations by one of us (C. D. A.) in cases of *S. viridans* bacterial endocarditis have shown that the renal lesion may persist after the infection has been eliminated. All this is in harmony with the evidence accumulated by Addis⁸ to the effect that glomerular nephritis, once under way, tends to propagate itself.

6. CONDITIONS IN WHICH PENICILLIN EITHER FAILS OR IS LIKELY TO BE INADEQUATE

Pneumococcal Meningitis.—Although pneumococci are often highly sensitive to penicillin, the results of treatment of pneumococcal meningitis have in our hands been unsatisfactory in many ways. These poor results are doubtless attributable in some degree to the nature of this infection⁹ with its well known tendency to adhesive arachnoiditis, encephalitis and thick gelatinous exudate, which impedes the local application of any therapeutic agent. Three patients with pneumococcal meningitis, probably of otitic origin, all survived their infection after intensive penicillin treatment given intrathecally, by injection into the ventricles and by intramuscular or intravenous injection, but in each instance serious neuropsychiatric residues reduced them to an essentially vegetative state. The following case is typical:

CASE 13.—A man aged 48, a gardener, was found comatose in his home two days before entry. He had previously been well. He was found to have signs of meningitis, and type 12 pneumococcus was grown from the blood and spinal fluid. He failed to improve on intravenous sulfadiazine and antipneumococcus serum and was sent into Stanford Hospital for penicillin. He was flushed, restless and delirious. The neck was stiff. There was some pus in the left auditory meatus but there were no signs of mastoiditis. He was started on large doses of penicillin by continuous intravenous drip, later changing to the intramuscular route (200,000 units per day). He also received 10,000 units in 10 cc. of saline solution intrathecally almost daily for the first eight days. On the ninth day, as he had not improved, the ventricles were tapped but there was no evidence of block. His temperature gradually subsided over twenty-six days, but the spinal fluid still showed cells and protein. After eleven days there was a relapse with slight fever and considerable disorientation, but pneumococci were not recovered from the spinal fluid. However, he was given more penicillin intramuscularly and four intrathecal injections of 5,000 units each. He remained mildly confused and had a peculiar visual difficulty characterized by ability to see objects but difficulty in naming them. He could read words aloud but could not read consecutively or understand what he read. At the time he left the hospital, two months after entry, the spinal fluid still showed increased cells and protein suggestive of arachnoiditis, but he was much improved. The temperature was normal. He was oriented and talked rationally for the most part. There was still a pronounced personality change with general mild mental deterioration. Six weeks after leaving the hospital there was not much change.

Poor results in this small series of cases should not be taken as a final evaluation of penicillin in pneumococcal infections and better results have been reported by others.¹⁰ However, our cases were treated intensively, both intrathecally, by ventricular puncture and by the intravenous and intramuscular routes and it seems unlikely that the outcome was due to too little treatment. Since sulfonamides are quite effective in pneumococcal meningitis, it may turn out that sulfonamides together with penicillin may be the best treatment for this condi-

tion. It seems especially important that some of our cases did not come under treatment until late in the disease. In the long run better results will undoubtedly be obtained if penicillin therapy is started on the first or second day of the meningitis.

Chronic (Staphylococcic) Osteomyelitis.—In contrast to acute staphylococcic osteomyelitis our results in most of the chronic cases have been unsatisfactory. If the lesion is in a long bone and can be laid wide open by surgical means, local penicillin irrigations seem to aid in rapid healing. In cases with sinuses leading into the pelvic bones or into the spine and inaccessible to surgery, neither local irrigations nor heavy intramuscular injections have had any definite effect in our hands.

CONDITIONS IN WHICH PENICILLIN WAS ENTIRELY INEFFECTIVE

During the course of our work penicillin was used in infections occurring along with other diseases, thus giving an opportunity to evaluate the material in conditions in which it ordinarily would not be used. The results agree with those obtained by others¹ but may be enumerated:

Tuberculous paravertebral abscess, no effect.

Lymphoid leukemia, no effect.

Alcukemic myeloid leukemia, no effect.

Infectious mononucleosis, no effect. (This condition developed in a patient with acute osteomyelitis while under active penicillin treatment.)

Mycosis fungoides, no effect.

Chronic (rheumatoid) arthritis, no effect.

Filariasis, no effect. (Blood count of microfilariae remained unchanged during penicillin administration.)

RELATION OF PENICILLIN FAILURE TO SENSITIVITY OF STRAINS IN VITRO

Even within categories of bacteria such as streptococci, staphylococci and others which are in general sensitive to penicillin there may be strains which are resistant in vitro. It is important to know whether such strain resistance in the test tube runs parallel with resistance to therapy in disease. It has been noteworthy that practically all of our strains of pneumococci, streptococci and staphylococci recovered from clinical cases of active infection were inhibited in the general range of 0.1 unit per cubic centimeter of culture medium. The relations with staphylococci are quite complicated and are discussed in detail in other papers from this clinic;¹¹ most of our penicillin resistant strains of this organism were recovered from sources other than active infections. There are strong suggestions, however, that some correlation exists between strain sensitivity in vitro and clinical response. This is well brought out in our series of 10 cases of subacute bacterial endocarditis caused by nonhemolytic streptococci. Eight strains were highly sensitive to penicillin in vitro, and all of the patients infected with these were promptly rendered bacteria free. In 1 of them culture made only two hours after penicillin was started was negative, as were all subsequent cultures. In the ninth case a strain was obtained which required two or three times the usual concentration of penicillin to produce inhibition in the test tube and with this patient intensive (200,000 to 300,000 units per day) treatment was carried on for nineteen days before the temperature began to fall, although blood cultures were

negative after penicillin was given. The strain from the tenth case was not inhibited in vitro even with very high concentrations of penicillin, and this patient failed to respond clinically to doses as high as 450,000 units per day, while blood cultures remained consistently positive.

It is evident, therefore, that failure of therapy in an individual case may be due to strain resistance, and the need of in vitro tests in routine work is emphasized.

We have not so far encountered the phenomenon of a strain becoming penicillin fast during the course of treatment, although this possibility has been raised both on experimental and on clinical grounds.¹² In a case of relapsing staphylococcic sepsis, for example, many positive blood cultures over a period of five months yielded organisms which were all equally sensitive even though treatment had been inadequate. It does not seem probable that induced penicillin fastness will turn out to be a major factor in clinical penicillin failures.

COMMENT

Penicillin failures fall under two main headings: First there are those diseases or infections which are entirely unaffected by penicillin. Those are now pretty well known and are enumerated in the memorandum¹ of the Office of Civilian Penicillin Distribution. Secondly there are the infections which in a general way are amenable to penicillin but in which special circumstances may lead to failure in the individual case. The present analysis deals with this problem.

Patients with infections by bacteria which are sensitive to the actions of penicillin may die or may relapse because of inadequate dosage. The daily amount may be too small, but the time factor is likely to be more important. This is clearly established in *S. viridans* bacterial endocarditis, and in hemolytic streptococcus and staphylococcus infections. A daily dose which may be adequate if given over periods of weeks or months may fail to cure if given for a few days only, even though the infection seems at first to be eliminated. We believe that the question of optimum dosage both as to frequency and as to size of daily injections and as to total duration of treatment is the most important practical problem in penicillin therapy at the present time.

The question of whether collections of pus can be disposed of by aspiration and injection of penicillin without surgical drainage is also one of great importance. In general the position seems secure that such surgical drainage will be necessary in addition to penicillin. This applies, in our experience, to empyema, lung abscess, subphrenic abscess and brain abscess, even though certain local collections caused by specially sensitive organisms (gonococci, pneumococci⁵) and located in favorable situations may be cured by aspiration and injection alone. Ordinarily if such a lesion is not cured or definitely improving after a week of injection therapy surgical drainage should be done. In some cases surgery is obviously necessary when the patient is first seen.

Penicillin may fail in infections with a highly sensitive organism even when given in huge doses. Under these circumstances either the patient is seen in a late stage of the disease or there is an overwhelming infection.

In general elimination of streptococcic infections by penicillin will not be followed by healing of an associated nephritis. In certain conditions, such as pneumococcic meningitis, the nature of the lesions makes adequate application of penicillin difficult, and serious neuropsychiatric sequelae are likely to result even if the infection is overcome and the patient lives. Chronic staphylococcic osteomyelitis of the spine or pelvic bones not amenable to wide surgical exposure has in our experience not been influenced by penicillin even though the strains are sensitive in vitro.

SUMMARY

Penicillin failures for the most part fall into the following groups:

1. Cases in which the treatment is too brief or the daily dose too small.
2. Cases in which penicillin fails unless surgical drainage is also done.
3. Overwhelming infection, even with a sensitive strain.

Penicillin may fail to prevent the development or progress of nephritis even if the predisposing (streptococcic) infection is eliminated.

Penicillin treatment of pneumococcic meningitis may be followed by chronic neuropsychiatric disturbances.

There is probably a correlation between strain sensitivity in vitro and clinical amenability to penicillin therapy.

Development of penicillin fastness probably plays little part in therapeutic failures.

THE TOXIC REACTIONS OF THE
NEWER SULFONAMIDES

CARL F. VILTER, M.D.

AND

M. A. BLANKENHORN, M.D.

CINCINNATI

In the past four years 1,936 patients in the medical wards at the Cincinnati General Hospital have been treated with sulfathiazole, sulfadiazine, sulfapyrazine, sulfaguanidine and succinylsulfathiazole. Sulfapyridine is now considered obsolete and is no longer used in this service, sulfanilamide is rarely employed and only a preliminary report can be given on sulfamerazine, since its use has been recent.

This particular study was undertaken to determine the relative incidence of untoward reactions to the various drugs and the relation of the mild and readily recognizable symptoms to severely toxic or lethal reactions. Difficulties were encountered in this evaluation because many patients admitted to this service are critically ill as the result of acute infection or are in a moribund state of chronic disease, and thus the division of symptoms due to drug and those due to disease is difficult. Also the drug is usually discontinued at the first sign suggestive of sulfonamide toxicity. Consequently the course from early and mild to late and severe symptoms can rarely be followed.

Table 1 shows the relative incidence of toxic reactions and of deaths due to and contributed to by sulfonamides. Persons treated at home and sent to the

hospital because of toxic symptoms are excluded, since this would yield an erroneous incidence of toxicity. Untoward symptoms caused by sulfadiazine are significantly less than those due to sulfathiazole and sulfapyrazine.

The symptomatology deserves some description and comment. Although the incidence may vary between one sulfonamide and another, the clinical picture is

* Not counting reactions or deaths that came after home treatment with sulfonamides.

much the same. Table 2 demonstrates the incidence of the various symptoms and syndromes. It includes patients referred because of sulfonamide intoxication.

Fever occurs most frequently between the fifth and tenth days of therapy. It is usually above 102 F. and, when chills occur, rises as high as 106 F. The fever may be of a plateau type or may mimic a septic source with daily elevations. In a small number of cases there is a relative bradycardia. The white blood cell count may be as high as 20,000 or may be within normal limits. Unfortunately there is no absolute method, short of discontinuing the sulfonamide, of differentiating such fever from that produced by the infection for which the drug is given. Frequently, however, there are clinical signs of resolution of the infection, or one is aided by the appearance of skin manifestations.

Skin lesions usually appear between the second and tenth days. Sulfathiazole usually produces a tender erythema nodosum, most frequently found on the extensor surfaces of the extremities and on the face. Sulfathiazole may also produce a morbilliform erythematous rash, either localized or widespread. This is similar to the lesions produced by sulfadiazine in 3 cases. The skin lesions may become pustular with continued administration of the drug.

Conjunctivitis, frequently associated with erythema nodosum, occurred only in patients treated with sulfathiazole in our series. It occurred between the fifth and fourteenth days and was bilateral in all but 1 case. The erythema and moderate edema of the bulbar conjunctiva may be accompanied by burning of the eyes and photophobia.

Nausea and vomiting, distressing symptoms that contributed to the discarding of sulfapyridine, occur infrequently with sulfathiazole and rarely with sulfadiazine. It usually appears after the first dose of the drug, in contrast to similar symptoms which may appear later as a result of uremia due to sulfonamide nephrosis or tubular obstruction. It is usually possible to change immediately to another sulfonamide with prompt relief of the emeses.

Polyneuritis, which is usually asymmetrical, has a remarkably high incidence. This may be due to the nutritional state of the patients of the Cincinnati General

From the Department of Internal Medicine, University of Cincinnati College of Medicine, and the Cincinnati General Hospital.
Read before the Section on Miscellaneous Topics, Sessions for the General Practitioner, at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 14, 1944.

Hospital.¹ Its onset with pains, burning, numbness or tingling has occurred as early as the seventh day of treatment and perhaps as late as six months after a course of sulfonamide.

Delirium is difficult to attribute to sulfonamides, since it occurs so frequently in febrile disorders. As a rule it occurs in association with other toxic manifestations of the drugs, particularly renal complications.

Polyarthritides and arthralgia appeared in a small number of our cases between the second and twelfth days.

Alterations in the blood and bone marrow were noted eleven times in the case of sulfathiazole, once with sulfapyrazine and not at all with sulfadiazine. Others have reported similar reactions with sulfadiazine, however, and we have seen it several times in patients not included in this series. These reactions may occur at any time in the course of therapy. Leukopenia gives no clinical sign. Thrombocytopenia is, of course, usually associated with hemorrhagic phenomena, hemolytic anemia with jaundice, and agranulocytosis with dirty ulcerations of the mouth and pharynx.

injury of the secreting portion of the kidney. In this paper we refer to the former as "calculi" or crystalline obstruction and to the latter as sulfonamide nephrosis. The former has been the most common in this series but has not caused death. All the fatal cases here described were due mainly to nephrosis.

Crystalline obstruction or "calculi" may be asymptomatic, but generally hematuria and sometimes renal colic appear from the second to the eighth day. These signs may be followed by drug retention, oliguria, albuminuria, anuria and uremia. In our group of 30 patients that developed this picture, the smallest dose was just under 3 Gm. of sulfathiazole. We believe a urine p_H of 7 or above and a high urine urea content aid tremendously in elimination of the crystals.

Sulfonamide nephrosis, characterized by drug retention, and a rising blood urea nitrogen may or may not be accompanied by oliguria and anuria and by albuminuria. It has occurred in patients receiving sodium bicarbonate. It may occur in conjunction with a systemic picture of encephalopathy, myocarditis, hepatitis, anemia, leuko-

sulfanilamide, sulfapyrazine and sulfathiazole.

None of the toxic symptoms are of particularly deadly portent. Most of them disappear within one to two days after discontinuance of the sulfonamide, except that neuritis may not. Leukopenia may disappear even while treatment with the sulfonamide continues. When the onset of peripheral neuritis occurs during treatment, the necessity of treatment must be weighed against the possibility of a persistent neuritis after recovery. Thiamine has not cured or prevented this form of neuritis. Some of our patients developed neuritis while receiving brewers' yeast, thiamine and liver extract. In others, vigorous treatment with vitamins and diet may have prevented neuritis from becoming worse.

Hepatitis, myocarditis and disorders of other systems undoubtedly occur, but as yet our clinical methods of evaluation are too limited to make it possible to be certain in their recognition.

The most troublesome toxic symptoms center about the kidney and the urinary tract. These have been the most dangerous to the patient and most difficult to diagnose in early stages. They appear in two separate forms but may overlap. The one is mechanical obstruction of the renal pelvis or ureter by crystals; the other is

cytosis and fever and is readily confused with Weil's disease when the history of sulfonamide ingestion is lacking. It appeared in 10 of the cases collected, and the smallest dose of drug (sulfathiazole) was 6 Gm. It was noted regularly between the first and fifth days that the first manifestation was a rising blood urea nitrogen level.

The treatment of renal complications must suit the individual case. Because of the frequency with which renal complications occur, daily fluid intake and urinary output, and frequent examination of the urine for erythrocytes and blood for drug level and nonprotein nitrogen should be a routine. For hematuria the urine should be alkalinized promptly by administration of sodium bicarbonate, and fluids should be administered to bring the urinary output to at least 1,200 cc. per day. If oliguria or retention of drug or nonprotein nitrogen develops, fluid intake should be increased, but if improvement does not result the drug should be discontinued. Ureteral catheterization is indicated if anuria is preceded by hematuria and renal colic. Only 1 of our patients has benefited by this procedure.

The value of routine alkali treatment concomitant with the sulfonamides is still open to question. Although it is true that sulfonamides are more soluble in alkaline

solutions and consequently might have less opportunity of depositing in the genitourinary tract, the increased rate of excretion tends to reduce the blood level of the sulfonamide to below effective range. Of the 30 patients with urinary complications due to sulfonamides, 11 had received alkali by mouth during sulfonamide administration. Four of these so treated were among the 11 who died. Five of the patients who died were given alkali by mouth or parenterally after the appearance of renal failure. Nine of the 11 were given parenteral fluids in an attempt to increase the flow of urine. Dehydration at this stage did not play a significant part.

were not considered to be of clinical significance and occurred infrequently. They included soreness of the neck and shoulder muscles, headache, dysphagia, weakness, malaise and pruritus.

Similar symptoms of toxicity apparently occur with sulfamerazine. Of 86 patients thus far given this sulfonamide, 9 have developed such untoward reactions. Three showed leukopenia, 2 fever, 1 delirium, 1 hematuria alone and 2 nephrosis. The majority of these patients suffered from pneumococcic disease.

Of the 1,936 patients included in the general report, the death of 4 (0.2 per cent) could be attributed mainly,

TABLE 3.—Deaths Due to Renal Complications of Sulfonamide Therapy in the Medical Wards of the Cincinnati General Hospital, January 1940 to April 1944*

Name	Age	Sulfonamide	Dose, Gm.	Diagnosis	Primary or Secondary Cause of Death	Early Signs and Symptoms	Late Signs and Symptoms	Autopsy
R. C.	75	Thiazole	22	Bronchopneumonia, arteriosclerosis and hypertensive heart disease, bronchial asthma	Primary	Oliguria, hematuria, general arteriosclerosis	Oliguria, hematuria, azotemia (blood urea nitrogen 165)	Sulfathiazole crystals in tubules and pelvis of kidneys and in ureters
V. C.	84	Thiazole	33	Bronchopneumonia, general arteriosclerosis, diverticulitis	Primary	General arteriosclerosis, poor hydration, microscopic hematuria, incontinence, oliguria	Increasing azotemia, drug retention, acidosis	"Acute pyelonephritis due to crystals"
M. T.*	42	Thiazole	6	† Pelvic disease	Primary	Maculopapular rash, stupor, fever, anemia, blood urea nitrogen 35	Oliguria, anuria, drug retention, blood urea nitrogen 105, fever, coma	Kidneys, multiple milky areas of necrosis; interstitial myocarditis with few milky areas of necrosis

G. J.	46	Thiazole	15	Bronchopneumonia, hemolytic streptococcus, empyema, hypertensive cardiovascular disease	Secondary	Severe hypertensive cardiovascular disease, urine white blood cells, casts, red blood cells prior to drug, blood urea nitrogen 42, drug blood level 27.5 mg. %	Blood urea nitrogen 140, drug retention, melena (uremic ?), anemia	None
E. R.	86	Diazine	55	Bronchopneumonia, pneumonia type III, arteriosclerotic heart disease	Primary	High level 17 mg. %, general arteriosclerosis	Progressive azotemia, confusion, stupor, coma	Acute bronchitis, bronchopneumonia, cardiac dilatation and hypertrophy; toxic myocarditis; arteriosclerosis; severe toxic nephrosis
H. S.	69	Diazine	51	Lobar pneumonia type I, bronchial asthma, chronic bronchitis	Primary	Arteriosclerosis, microscopic hematuria	Gross hematuria, oliguria, blood urea nitrogen 70	None
R. F.	41	Pyrazine	99	Staphylococcal septicaemia	Secondary	Drug level 20 mg. %, oliguria, blood urea nitrogen 59 %	Rising azotemia, anuria, coma	Sulfapyrazine crystals in renal calices, pelvis, cortices and medullas and ureters

* Including patients treated at home

A patient who has toxic symptoms from a specific sulfonamide need not necessarily display signs of toxicity with another. In this series we have been able to find 6 instances in which initial treatment with sulfathiazole resulted in rash, fever, nausea and vomiting or hematuria. All 6 were changed directly to sulfadiazine. In 4 the untoward reactions including hematuria, subsided immediately. In 2 (fever, rash) the toxic symptoms recurred.

In 2 instances in which sulfadiazine produced azotemia, sulfathiazole was substituted after omission for a few days. The azotemia did not recur. In 1 case, however, after 90 Gm. of sulfathiazole, fever, cutaneous lesions and conjunctivitis appeared.

Numerous minor subjective complaints appeared which could be attributed to the sulfonamides. These

perhaps solely, to the action of the sulfonamides. In 5 more instances death was probably hastened by the administration of sulfonamides. To this group are added 2 cases of sulfathiazole intoxication with resultant death in which the drug was given in the home by a private physician. All these patients died with renal complications due to sulfonamides. Six necropsies were performed in this group of 11 deaths.

Table 3 shows the pertinent clinical data including autopsy. In the 6 cases thus examined, obstruction of the pelvis or ureter did not occur. Crystals were recorded as the evidence of sulfonamide intoxication, but crystals or calculi did not obstruct. None of the patients examined post mortem were anuric.

Five of the cases might be classed as nephrosis. In only 2 of these was there an early manifestation of

sensitivity; i. e., in 1 a typical rash developed and in another nausea and vomiting were noted from the first dose.

There were certain signs and conditions in these individuals which warned against indiscriminate use of sulfonamides. Five showed advanced arteriosclerosis and 2 impaired renal function. The earliest manifestations of unfavorable action of the drug were varied and seldom subjective—usually microscopic hematuria, oliguria, incontinence and drug retention. None had renal colic. The signs of uremia later developed.

Although the blood urea nitrogen is one of the most useful of indexes in this problem, its magnitude has apparently little relation to the survival or recovery of the azotemic patient when the drug is discontinued. In one individual who recovered, the blood urea nitrogen rose to 135 mg. per hundred cubic centimeters. In another it was 70 mg. per hundred cubic centimeters on the day of death. Seventeen of those with genitourinary complications who recovered had blood urea nitrogen levels over 50 mg. per hundred cubic centimeters. It has been routine in this medical service to measure the urea nitrogen on all patients before and during treatment with sulfonamides. An initial level as high as 70 or 80 mg. per hundred cubic centimeters does not defer cautious treatment of acute infectious disease. Should the level of nitrogenous products rise constantly however during sulfonamide therapy, it is wise to discontinue the drug regardless of the drug blood level.

It is apparent, then, that with advanced age and renal disease sulfonamides should be prescribed cautiously and the treatment followed carefully. With the onset of persistent hematuria, decreased urine output, signs of azotemia and unusually high levels of sulfonamide in the blood or of any one of these manifestations, treatment should certainly be discontinued.

It is obvious that the early signs of severe reactions are so occult as to be revealed usually only by laboratory studies. There is nothing, unfortunately, that bedside appraisal of the patient will yield in the early diagnosis of the fatal sulfonamide reaction.

SUMMARY

Among 1,936 patients toxic reactions were recorded among 116, an incidence of 6 per cent. These reactions were usually of such severity as to compel the arrest of treatment. Occasionally treatment could be resumed by changing to another drug. This could be done oftenest by changing from sulfathiazole to sulfadiazine.

Death was ascribed to toxic effects mainly in 4 instances (0.2 per cent) and death in 5 was certainly hastened by drug intoxication. All fatal toxic reactions were mainly renal and resulted in uremia.

In no instance was blockage of the pelvis or ureter thought to be the cause. There was no correlation of the milder forms of intoxication to the more severe or lethal.

Therefore there are no premonitory signs of renal intoxication. Mild signs of disease of the kidney pelvis are microscopic hematuria, oliguria, incontinence, pain and elevated blood urea.

If these signs are observed, sulfonamide treatment should be stopped or continued with great care lest nephrosis occur. The use of alkali and water usually corrects mild symptoms. By the time classic symptoms of uremia appeared, no form of treatment was effective.

In this series blockage of the renal tubule was considered the cause of death; hence ureteral catheterization was not helpful. In disease of the tubule, symptoms may be absent until the disease is well established and irreversible.

ABSTRACT OF DISCUSSION

DR. LAWRENCE D. THOMPSON, St. Louis: Few reports have covered such a large series of cases and have been so well analyzed as this report by Drs. Vilter and Blankenhorn. The comparative incidence of reactions with the various drugs agrees closely with the majority of reports. The report of Hageman, Harford, Sobin and Ahrens from our clinic revealed little difference in the incidence of reactions following the use of sulfadiazine and sulfamerazine. My own observations, although covering a series only about one third as large, are in close agreement with those reported, with a possible exception in the cases of renal complications; the incidence of these complications has been somewhat smaller. It is accepted that age and preexisting renal damage predispose to renal complications following the use of sulfonamide drugs. Since most of the cases were observed in the St. Louis City Hospital, this series should be comparable to that of Vilter in respect to this factor. The forcing of fluids is also a generally accepted part of sulfonamide therapy. The deliberate limiting of fluid intake in order to secure a high blood level of the drug early in the course of treatment is to be condemned most emphatically; unfortunately, this tendency has appeared repeatedly during the past year. The use of sodium bicarbonate may have contributed to this difference in results. The wisdom of the routine use of sodium bicarbonate is still under debate. The increased solubility of the drugs in alkaline urine is undisputed. The early observations of Hartmann and his co-workers, which indicated the harmful effect on the kidneys of an alkalosis combined with the use of sulfanilamide and sulfapyridine, made such an impression on me that only rarely have I given sodium bicarbonate. Later studies have made it clear that sulfanilamide and the more recent sulfonamides cannot be compared in many respects. Perhaps it was an error to apply this rule with the use of sulfathiazole and sulfadiazine; however, like sulfanilamide, these drugs are reabsorbed to a significant extent by the renal tubules. This reabsorption has been shown to be an active process by the tubular cells. The harmful effect of either acidosis or alkalosis on already impaired tubular cells has been pointed out by many students of renal physiology and pathology. Until more exact information is available, it is logical to assume that two agents, each of which in itself may impair renal tubular function, should not be used together except for some very special purpose and then under most careful observation. The repetition of observations on the toxicity of these drugs, particularly as to the effect on the renal tubules, such as the work of Shannon under the experimental condition of deliberate alkalosis, might throw some light on this debated point.

DR. S. L. BERNSTEIN, Cleveland: What is Dr. Blankenhorn's opinion of the administration of the sulfonamide drugs on ambulatory patients? I recall giving a man aged 60 a small dose of sulfanilamide for a septic throat, without a culture. He had a total of 20 grains (1.3 Gm.), with alkali, for three days. He had to be urged to go to the hospital because of agranulocytosis. Fortunately, he recovered. Since then I have been chary about prescribing sulfonamides to ambulatory patients. One sees many prescriptions at the drug stores, with doctors prescribing them for ambulatory patients. The druggists are beginning to prescribe them over the counter, and this is becoming a serious question.

DR. DAVID LEHR, New York: In experiments on the prevention of renal obstruction, the animals received repeated intraperitoneal injections of sodium sulfadiazine in amounts known to produce massive precipitation of sulfadiazine in the renal tubules, provided no therapy was employed. Stomach tube feedings of water alone did not provide adequate protection. Animals of this group succumbing to the sulfadiazine intoxication revealed without exception massive intratubular precipitation

of sulfadiazine accompanied by severe tubular dilatation and degeneration of the kidneys. The striking success of alkalization (sodium bicarbonate) in combination with the "forcing of fluids" was clearly borne out by the high rate of survival (no death) and the almost complete absence of significant pathologic lesions in the alkali treated animals. These measures were of little value once the renal obstruction was fully developed. In such instances the "forcing of fluids" actually produced water poisoning. In the treatment of renal obstruction, standardized experimental conditions were established in the following manner: The renal block was produced by intraperitoneal injection of a single fatal dose of sodium sulfadiazine. If left untreated, the animals invariably developed pronounced renal obstruction from intratubular precipitate of sulfadiazine, and 80 to 90 per cent succumbed to this complication after two to three days. Treatment consisted in stomach tube feedings of fixed amounts of water or salt solutions (containing either sodium bicarbonate, ammonium chloride, a mixture of these two or sodium chloride). The most striking result was achieved with solutions of sodium chloride and of the mixture of sodium bicarbonate and ammonium chloride. They made possible the complete recovery of all rats from an otherwise fatal sulfadiazine intoxication, whereas no benefits were derived from the "forcing" of water alone. The water-sodium bicarbonate combination even shortened the time of survival (alkalosis), and ammonium chloride, in addition to a further reduction of the life span, also increased the mortality to 100 per cent (acidosis). Apparently water alone is reabsorbed rapidly under the conditions of a block in the collecting tubules, whereas in the presence of salts of high osmotic value some of the water might be forced to remain in the tubules, dilate them and push the tubular plugs down and out of the kidney. The life saving effect of salt diuresis in renal obstruction from sulfadiazine has been learned in experiments with more than 200 animals.

DR. M. A. BLANKENHORN, Cincinnati: Dr. Thompson and I come to the same consideration of the problem of the general practitioner who gives sulfonamides; namely, damage to the kidney. The matter of making alkalis mandatory with sulfonamide medication is a weighty one, and being responsible for rather a large service with a great variety of patients and a great variety of house officers, I am unwilling to make it mandatory in the service for the reasons of which Dr. Thompson mentioned a few. Perhaps we might have improved our service had we been able to give alkalis intelligently. Merely to exhibit alkalis to the patient is far from meeting the indications of alkalizing urine. Alkalis may be given in too great an amount, and they may be given in an insufficient amount. The object is to alkalize the urine. We used nitrazine paper to test the urine, when freshly voided, as our criterion of alkalization. That is a simple device which any general practitioner can put into the hands of his nurse. Litmus paper is not reliable. I may have been misleading in my discussion of the treatment and the prophylaxis of renal complications in mentioning water. Dr. Lehr, when I said "water" I meant water as a vehicle for glucose, saline, alkali in the form of bicarbonate and lactate. To answer Dr. Bernstein on the use of sulfonamides for ambulatory patients, if I should draw on my own experience I would be absolutely against it. I have seen individuals carried into the hospital in a desperate condition, and I have not counted the deaths that I have seen in other hospitals where ambulatory patients had been treated or received. There are several in my experience, and my advice would be not to give it to ambulatory patients. I am not unfamiliar with Dr. Lehr's work and with the work of others who have concentrated on the function of the tubule and its reaction to this drug, because that is where the work must be done, and it is from such experimentation that the answer may come. The use of alkalis in moderate dose, in advance of treatment or with treatment, will not always prevent fatal damage to the kidney. I speak particularly of that lesion of the kidney which involves the parietal structure of the kidney, as well as the tubule. That is a cellular infiltrate resembling granuloma. Just why that lesion occurs, I do not know. Two of the patients not counted in this series that I have seen had that disorder of the kidney from relatively small doses. That was the unfortunate individual who is sensitive to the dose and has perhaps an allergic reaction.

AND

WILBUR K. SMITH, M.D.

ROCHESTER, N. Y.

The total time interval required for essential agreement on some phases of infantile paralysis includes the names of Heine,¹ Medin,² Wickman,³ Lovett⁴ and many others. During this period and since that time a steady flow of literature has provided evidence of the great efforts which have been made in the study of all aspects of a disease which annually disables great numbers of children and adults.

Out of all this there came the confirmation of a correlation between the pathologic changes and the clinical characteristics of infantile paralysis. Thus it became established that the disabilities provoked by this disease were directly proportional to the degree and extent of permanent damage to the lower motor neurons on which normal muscle function was dependent.

Spasm in the muscles of the neck and back, the spine sign, was a noted characteristic of early onset. Hyperesthesia was less frequent but carefully distinguished from muscle soreness, tenderness and pain. The latter usually prevailed but was most variable as related to degree and duration.

In 1916 Lovett⁵ and, more recently, Ober⁶ and others have recorded the observation that moist heat relieves muscle pain and soreness. The prescription of rest for the affected extremity was then logically based on principles which are today recognized as sound practice in all phases of clinical medicine and surgery.

When considered as a unit, each of three parts, (1) the pathologic characteristics, (2) the clinical manifestations and (3) the treatment, were related so naturally in the form of a premise that they have held together with ease for more than three decades.

But none of us would hesitate to divorce ourselves from this or any other premise when presented with the evidence that it was wrong. However, any logical premise which has slowly developed from the work of many men in various countries should not be readily discarded on the basis of a different opinion which depends solely on clinical observations relevant to some particular manifestation of a disease.

This brings us to Sister Kenny's concept of infantile paralysis. It is based on her personal observation of

patients during and after the acute stage of the disease. In Pohl's⁷ most recent book on the subject it is stated that:

Infantile paralysis is neither a simple disease nor one completely understood. The destruction of anterior horn cells of the spinal cord is certainly not the principal nor the most important characteristic and does not explain the presenting symptoms of the disorder. From the discussion presented, infantile paralysis affects both muscles and nerve tissue and is a disease capable of widespread disorganization of the neuromuscular system. The condition of muscle spasm is the symptom common to all cases. Untreated spasm destroys muscle tissue and is the cause of contractures, stiffness and deformities. In addition, the pathophysiological symptoms of mental alienation of muscle and incoordination of muscle action implicate the more highly organized portions of the nervous system. Paralysis is unfortunately a feature of the disease, but paralysis proves after all to be a minor consideration in most cases of infantile paralysis. Muscle spasm, mental alienation and incoordination are far more damaging to bodily mechanics. Acceptance of these true symptoms forms the true basis on which the treatment of the disease can be designed. Only meticulous attention to all of the disturbed structures can reduce the evil after-effects of the disease.

Spasm . . . if untreated will result in permanent muscle damage, stiffness and skeletal deformities.

. . . muscle spasm in the acute stage appears almost to have the properties of an acute inflammatory process capable of causing serious and permanent changes in the muscle substance.

. . . the examination of the patient should not include stretching, squeezing or manipulation of the affected muscles, nor should the patient be requested to make any voluntary efforts at contraction of the muscle.

It is recognized that certain muscles, noticeably the opponents of the muscle in spasm, have become nonfunctioning. This is of no immediate concern, since these nonfunctioning muscles usually are simply alienated. Such muscles, however, cannot be restored except by first treating the condition of spasm in the opponent. Attempts to determine the presence or absence of contractile power in muscle are therefore not only impossible and of no value, but they have the serious effect of increasing the spasm in the affected muscles. Under no circumstances should the acutely ill patient be encouraged to contract any of his muscles for the purpose of recording the so-called muscle test.

Inspection or observation alone usually suffices for the purpose of analysis of the muscle condition.

Critical examination of infantile paralysis in the acute stage will present abundant evidence to show that orthodoxy has erred both in the recognition as well as in the interpretation of the physical findings of the disease.

Miss Kenny's real contribution is not a new treatment for the disease of infantile paralysis as it has been conceived in the past but a conception of the disease itself so radically opposed to the old as to almost warrant considering the entity as a new disease. The basic principles . . . [are] . . . built upon observations of the behavior of the musculature.

In short, Miss Kenny's discovery is that infantile paralysis is a disease in which disturbance of physiological function of the nervous system is of more importance than actual architectural change. Many of the observable clinical phenomena are the result of functional disorganization of the motor centers and of the nerve pathways to the muscles. The disease affects muscle as well as nerve tissue. Muscle spasm is the primary lesion in the disease rather than paralysis. Miss Kenny has designed a treatment for these conditions. Needless to say, the treatment could have nothing in common with the previous methods, designed for a disease of opposite conception.

Any concept such as this one should not be accepted or rejected on the basis of clinical observation alone. An objective analysis of the new versus the old concept revealed a common agreement on one point; i. e., neuromuscular dysfunction was the cause of disabilities and therefore continued to be the reason for the great efforts made to bring infantile paralysis under control. This point in common should therefore lead to agreement that a lowering of incidents of disabilities, subsequent to the acute onset of the disease, is dependent on the discovery of more effective methods of preventing the impairment of muscle function. From this point it naturally follows that a continuation of past efforts toward this objective might be favored by additional information regarding the behavior of the neuromuscular mechanism in the acute stage of infantile paralysis.

It therefore became our purpose to investigate the characteristics in the behavior of the neuromuscular mechanism, primarily as related to the acute stage of infantile paralysis, for comparison with the recorded characteristics of normal individuals and the records of patients with other established neuromuscular disabilities. In so doing it was indicated that we should pay particular attention to any and all evidence through which the significance of muscle spasm might be evaluated.

Here we venture to state that a similar point of view may have prompted the electromyographic studies made by Watkins, Brazier and Schwab.⁸ It was gratifying to note the agreement between their recorded evidence and that which we reported in 1942.⁹ This fact is far more important than that we offer a slightly different explanation for the recorded abnormal functions of the lower reflex arc.

With the introduction of muscle spasm as the dominant influence contributing to disability, the authors previously quoted also accepted the possibility of paralysis on the basis of established evidence of partial damage to or complete destruction of the lower motor neuron innervation, in part or in toto, to one or more muscles. The absence of conclusive evidence in support of the statements which have been quoted regarding muscle spasm cannot be regarded as evidence that spasm might not play a significant role in producing disabilities. However, the clinical and myographic records of muscle spasm in the acute stage of infantile paralysis should not be interpreted as evidence which confirms the "new concept" as quoted.

But this "new concept" has already been found to be at variance with the distribution of spasm as recorded by action currents through the oscillograph. Our original report and that of Watkins, Brazier and Schwab emphasized that muscle spasm in the acute stage of infantile paralysis was not limited to the "antagonists of nonfunctioning muscles." On the contrary, both of these investigations gave evidence which emphasized the presence of spasm in the "nonfunctioning" or weakened muscle and in muscles which showed no clinical or other evidence of weakness, as indicated by successive records from respective patients.

In attempting to clarify this situation we have found that available methods for evaluating the role of muscle spasm are very limited. But it is evident that both mus-

cle weakness and muscle spasm are respective states of abnormal function which are expressed through the lower motor neuron. To differentiate between these two states of abnormal muscle function it was found that action current records provided the most useful evidence.

Four action current amplifiers were constructed for use with a multiple recording oscillograph, for making records of the reaction on one or a maximum of four muscles simultaneously, to stretch reflex or voluntary contraction.

A total of 50 individuals have been studied: normal subjects 9, spastic paralysis patients 6, infantile paralysis patients 23, miscellaneous patients 12. The total number of records has been from Nov. 22, 1941 to July 1, 1943 3,622 and from July 1, 1942 to July 1, 1943 2,879.

The past year's work has added confirmation to the summary of recorded evidence reported in 1942 and provides a more lucid interpretation of this evidence than has heretofore been possible. Naturally this approach directs primary attention to prevailing abnormalities in the function of the neuromuscular mechanism of the lower reflex arc during the acute stage of infantile paralysis.

However, a satisfactory understanding of the recorded reactions which are to be enumerated cannot be provided by the simple concept of upper and lower motor neurons without designation of the mechanisms which may be altered by the direct or indirect effect of the virus of infantile paralysis to produce the respective abnormal functions.

Interpretation in this instance should be based on the present available information concerning the intrinsic structures and function of the normal lower reflex arc. This should include information concerning the normal structural and functional relationships which the lower motor neuron bears to other nerve cells at its own and at other levels; i. e., its relation to all neuronal pathways which make essential contributions to every physical effort that requires muscular coordination.

As this information is still in a formative state, our interpretation must be based on the knowledge which is available at the present time.

As part of the spinal reflex arc and as the effector cell of "the final common path," the lower motor neuron plays an obviously essential role in all reflex and voluntary contractions of skeletal muscle. The fact that the lower motor neuron can be excited to discharge by impulses passing over the dorsal spinal nerve roots is axiomatic. That these dorsal root impulses can excite the cell directly or through the medium of interneurons seems established by the investigations of Renshaw¹⁰ and of Lloyd.¹¹ In addition, the lower motor neuron is bombarded by volleys of impulses passing over pyramidal and extrapyramidal pathways, these impulses reaching the motor neuron probably through the medium of interneurons.

It is important for the lower motor neurons to respond to impulses which reach them, but it is just as important that these same neurons at times should be rendered inactive. An example of this phenomenon is the well known fact that under certain circumstances sensory impulses passing into the spinal cord are pre-

vented from exciting the lower motor neurons to discharge, and these sensory impulses may even block or nullify the effect of other impulses impinging on the motor neuron from other levels of the nervous system. This phenomenon of inhibition leads to the relaxation of antagonists during the performance of muscular movements and thus facilitates their proper execution. At present we have no generally accepted explanation of the mechanism of the inhibitory process. It appears that the functional reaction of the lower motor neuron as related to transmission of impulses by way of the axon to striated muscle fibers is determined by some mechanism at or related to internuncial cells or to the many synapses associated with the dendrites and cell body of the lower motor neuron.

Fig. 1.—Diagram showing some of the descending pathways which influence the spinal motor neuron: C, caudate nucleus; C. P., cerebral peduncle; G., globus pallidus; I. C. P., inferior cerebellar peduncle; N. R., red nucleus; P., putamen; S. C. P., superior cerebellar peduncle; S. N., substantia nigra; Th., thalamus; Ves. N., vestibular nerve.

In figure 1 some of the pathways through which the lower motor neuron receives a multiplicity of inhibitory and excitatory impulses are diagrammatically indicated.¹² The large number of synaptic connections which the lower motor neuron makes with internuncial cells and the axons of dorsal root ganglion cells is in sharp contrast to the single axon over branches of which the former sends impulses to more than one hundred muscle fibers at the rate of five to ten per second for the maintenance of normal tone and at a greater frequency for increased muscular contraction.

When considered as a unit, the cell body of the motor neuron, while making numerous synaptic connections, is regarded as essentially free from structural connec-

12. Although we use the term inhibitory impulses, there is no evidence to indicate that impulses causing inhibition differ in any way from those causing excitation.

However, as related to the latter point our attention must continuously be focused on the functional disturbances of the lower reflex arc as they have been found to prevail in relation to muscle spasm with or without muscle weakness, during the acute stage of

These characteristics of muscle spasm, which we have recorded in almost every instance, have usually been of such low magnitude that there was seldom agreement between various individuals on clinical examination. However, we have on rare occasions seen intermittent contractions in an anterior tibial muscle. The tendon became prominent at the rate of ten to fifteen times per minute, for a period of twenty minutes in one

ceps muscle, which contracts to produce extension at the knee joint. The investigations of Renshaw¹⁰ and of Lloyd¹¹ show that within a single spinal segment the large nerve fibers conducting afferent impulses from muscle receptors over the dorsal spinal roots synapse directly with the lower motor neuron without the mediation of internuncial cells, thus creating a two neuron arc reflex pathway. In contrast, reflex discharges over the ventral roots, as a result of impulses

instance. The boy, aged 6, stopped crying when the spasmodic contractions of the anterior tibial muscle ceased.

But evidence of spasm was never present when a muscle literally failed to give any action current response to the stretch reflex. In all such instances the muscle was considered as completely paralyzed at the time the record was made. This was regarded as an important observation. It provided a starting point from which we begin to answer questions regarding the evidence of spasm when it is expressed in association with weakened muscles or muscles of normal strength.

From this finding we may conclude that the prevailing evidence of spasm is not due to the intrinsic reaction of muscle fibers as it has been described in association with inflammation or the fibrillation which is said to follow section of the motor nerve to a muscle. We are therefore forced to conclude that in this instance the muscle is deprived of all motor impulses without any associated muscle fiber contractions. An oscillographic record of a completely paralyzed muscle showing no evidence of action current reaction to a stretch reflex is illustrated in figure 5.

The characteristic pattern of a weakened muscle's reaction revealed that its response to voluntary contraction stimulus was often less than the spasm which followed stimulation by stretch reflex.

Fig 5—Patient with infantile paralysis. The reaction to stretch in a completely paralyzed muscle (right anterior tibial), i. e. muscle which shows no evidence of action currents in maximal voluntary effort.

This has been found to be a common behavior of weakened muscles. There are two plausible interpretations: (1) that more lower motor neurons are stimulated by the stretch reflex than the number which is activated by the voluntary effort to contract the weakened muscle; (2) that, although an equal number of lower motor neurons are stimulated in each instance, a greater number of impulses are induced by the stretch reflex than result from voluntary effort.

This evidence further indicates that voluntary impulses from proximal centers may be more effectively blocked than the sensory impulses which are stimulated by the stretch reflex. From this, therefore, one might conclude that the damage of lower motor neuron cells is not as great as the initial loss in voluntary function would indicate. From this it would follow that impairment of muscle function in the acute stage of infantile paralysis may be due to any one or any combination of the following causes: (1) injury or death of the lower motor neuron cell body; (2) partial or complete block of voluntary impulses from higher centers without damage to the lower motor neuron cell; (3) inhibition of contraction due to the presence of impulses arising within the muscle, i. e. muscle soreness and pain, and that muscle spasm does not initiate the development of muscle weakness as indicated by clinical observation and the following action current records.

The "nonfunctioning" or weakened muscle usually produces a characteristic pattern in response to voluntary and reflex stimulation. The voluntary contraction

of the left gastrocnemius muscle, free from clinical evidence of weakness, is illustrated in figure 6 A. The voluntary contraction of the weakened right gastrocnemius muscle, same patient, is illustrated in figure 6 B. It is apparent that there was much less response in the weakened muscle than in the normal muscle. On

Fig 6—Patient with infantile paralysis. A, record of maximal voluntary contraction of relatively normal left gastrocnemius muscle; upper line, action currents of left gastrocnemius; lower line, signal indicating duration of movement. B, record of maximal voluntary contraction of weakened right gastrocnemius muscle; upper line, action currents of right gastrocnemius; lower line, signal indicating duration of movement.

Fig 7—Same muscle as figure 6 A, record of reaction to passive stretch; upper line, action currents of left gastrocnemius; lower line, signal indicating duration of stretch. B, same muscle as figure 6 B, record of reaction to passive stretch (stretch reflex); upper line, action currents of right gastrocnemius; lower line, signal indicating duration of stretch.

stretch reflex of the muscle with normal strength a low magnitude of spasm, as previously defined, was recorded as in figure 7 A, while the stretch reflex of the weakened muscle, figure 7 B, produced spasm greater in degree than the reaction of the same muscle to voluntary effort as recorded in figure 6 B.

In either situation it follows that estimation of the voluntary contraction strength of a weakened muscle does not provide a reliable index of the total capacity of the lower motor neurons which activate the muscle.

As a companion to this reaction there was another which was unanticipated. When the stretch reflex

Fig. 8.—Patient with infantile paralysis: *A*, reaction in left anterior tibial and gastrocnemius muscles to stretch of left anterior tibial muscle; upper line, action currents of left anterior tibial muscle; middle line, action currents of left gastrocnemius muscle; lower line, signal indicating duration of stretch; *B*, records from same muscles, record of passive stretching of left gastrocnemius

Fig. 9.—Patient with infantile paralysis: Record of action currents of both anterior tibial and gastrocnemius muscles in passive stretch applied to left gastrocnemius; top line, action currents of left anterior muscle; second line, action currents of left gastrocnemius; third and sixth lines, action currents of stretch; fourth line, action currents of right anterior tibial; fifth line, action currents of right gastrocnemius

reaction of a weakened left anterior tibial muscle was recorded simultaneously with its antagonist, evidence of spasm was definite in the records of respective mus-

cles (fig. 8 *A*). Likewise when the gastrocnemius was subjected to stretch reflex, there was recorded evidence of spasm in both the weakened muscle and its antagonist as illustrated in figure 9 *A*. This evidence has been interpreted as a reversal of Sherrington's principle of reciprocal innervation. The action current response of a normal left anterior tibial muscle to a stretch reflex applied to its antagonist, the left gastrocnemius, is illustrated in figure 10.

It was observations such as these which emphasized the need for recorded evidence of the reaction of four muscles simultaneously when the stretch reflex was applied to one of the four. Action current records were therefore made as indicated in figure 9. In this instance the stretch reflex was applied to the left gastrocnemius and evidence of spasm was recorded in both the gastrocnemius and the anterior tibial on the left leg and in the corresponding muscles of the right leg. The prevailing evidence of spasm in muscles of the side opposite to the applied stimulus is in sharp contrast with the corresponding reaction of normal muscles as indicated in figure 12. We have also found that the same cross stimulation was provoked by voluntary contraction of the left gastrocnemius, figure 13. A diagrammatic expression indicating how the prevailing dysfunction may provoke this particular behavior on the part of the lower reflex arc is presented in figure 11.

Fig. 10.—Record of same muscles as in figure 8 in a normal person on passive stretch applied to left anterior tibial

The evidence presented, therefore, indicates that during the acute stage of infantile paralysis the normal function of the lower reflex arc is grossly altered. Such alteration is clinically expressed by partial or complete loss of muscle function. It is also revealed in action current records indicating the presence of spasm in weakened muscles and muscles of normal strength, when respective muscles are stimulated by stretch reflex. It is further emphasized by reversal of the Sherrington reciprocal innervation together with cross stimulation of agonist and antagonist when one of the corresponding muscles on the opposite side is stimulated by stretch reflex or voluntary contraction. But it should be emphasized that this recorded evidence of altered function, (1) spasm, (2) reversal of the Sherrington reciprocal innervation and (3) cross stimulation, all gradually disappeared subsequent to the passing of muscle soreness and pain, which is not always present but when present is always first to disappear. If and when disabilities prevail in the postacute stage, they are expressed in terms of muscle weakness or complete paralysis, usually the former, without clinical or recordable evidence of (1) spasm, (2) reversal of the Sherrington reciprocal innervation or (3) cross stimulation herewith described.

It is during the earlier months of the postacute stage that initially paralyzed muscles may show some return of function and weakened muscles usually regain an appreciable percentage of normal strength. It has been emphasized for fully three decades that such spontaneous improvement is most likely to express itself during the first six months after onset, the rate of improvement thereafter declining during the next six to twelve months.

Such evidence of improvement in strength of a weakened muscle is revealed in action current records of voluntary contraction against resistance of the observer's hand (fig. 14 *A* and *B*). We have found that muscle spasm, stimulated by stretch reflex, diminishes during this period (fig. 15 *A* and *B*). But it does not follow that the disappearance of spasm is necessarily accompanied by full restoration of strength in the weakened muscle. Action current records of weakened muscles, made one to four years after onset, revealed the weakness of voluntary contraction but failed to show evidence of spasm in any of the various manifestations herewith presented as common to the acute stage.

From the interpretation of records let us turn to the clinical record on which the Kenny concept is solely dependent. In 1932 work done by the International Committee on Infantile Paralysis¹³ represented a critical analysis of more than 8,000 references. All authorities agreed on the high incidence of muscle spasm in

of muscle weakness or paralysis if and when either became apparent. But the presence of muscle spasm in the extremities was not noted and emphasized as it was in relation to the neck and back.

Moreover, from the inverse relationship of the maximum degree of muscle spasm prevailing in the acute

Fig. 12—Records from same muscles as in figure 9 in a normal person on passive stretching of right gastrocnemius

stage of infantile paralysis and the least percentage of weakness or paralysis in the neck and back muscles there was no indication that this spasm was the primary cause of the disabilities which create fear of this disease.

From the available conclusive data we establish the following points:

1. In some patients spasticity has been recorded in all muscles which we have investigated
2. Evidence of spasticity has been recorded from (a) weakened muscles, (b) the antagonists of weakened

Fig. 13—Same patient as in figure 9. Action currents of same muscles obtained during voluntary contraction of left gastrocnemius

muscles and (c) muscles which exhibit no clinical or other evidence of weakness.

3. The evidence does not support the view that fibrillation or inflammation of the muscle is responsible for the spasticity.

Fig. 11.—Diagram showing some of the neurons involved in a spinal reflex. Only one level of the second to fourth lumbar region which contributes to the knee jerk is shown. Other levels of the spinal cord show similar connections. For explanation see text.

the neck and back as characteristic of the early onset of infantile paralysis. But despite this fact it was also noted that the incidence of muscle function impairment in the neck and back was much less than at any other levels of the body. Wernstedt's¹⁴ figures on 5,948 cases are typical of the percentage distribution of Lovett and other authorities: cranial nerves 13.3 per cent, throat and neck muscles 5.8 per cent, trunk 27.8 per cent, arm 41.3 per cent and leg 78.6 per cent. Lovett's¹⁵ total of 1,529 cases gave the following distribution: one or both legs (with or without one or both arms) 83.3 per cent, one or both arms (with or without one or both legs) 38.7 per cent, abdomen 72.0 per cent, back 13.5 per cent and neck 11.0 per cent.

The common stiffness and less frequent rigidity of the neck and back was invariably accompanied by muscle soreness and pain. The presence of the latter in the extremities was noted to prevail before the onset

13. Poliomyelitis: A Survey Made Possible by a Grant from the International Committee for the Study of Infantile Paralysis, Baltimore, Williams & Wilkins Company, 1932, p. 173.

14. Wernstedt, W.: Klinische Studien über die zweite grosse Poliomyelitis-Epidemie in Schweden 1911-1913. *Ergebn. d. inn. Med. u. Kinderh.* 23: 705, 1924; *Epidemiologische Studien über die zweite grosse Poliomyelitis-Epidemie in Schweden 1911-1913*, ibid. 26: 248, 1924.

15. Lovett, R. W.: *Treatment of Infantile Paralysis*, ed. 2 Philadelphia, P. Blakiston's Son & Co., 1917, p. 7.

4. On stretching the antagonist of a weakened muscle, the evidence of spasticity in the weakened muscle is frequently greater than the recorded reaction of the muscle in response to voluntary contraction.

5. On stretch reflex of a weakened muscle, spasticity not only is recorded from its antagonist but also is significantly present in records of the corresponding muscles of the opposite extremity.

6. In association with voluntary contraction efforts this spasticity spread was recorded from the same group of muscles as resulted from stimulation by stretch reflex noted in 5.

7. But a muscle which shows no clinical evidence of weakness always produces a stronger voluntary contraction record than the recorded evidence of muscle spasm.

8. There has never been recorded evidence of spasm when a muscle failed to produce a record of reaction to the voluntary movement.

9. Spasticity is a generalized phenomenon in the early stages of infantile paralysis.¹⁶

10. As prevailing spasm diminished in a weakened muscle, there was recorded evidence of increased strength in the voluntary contraction.

11. The gross initial spasm of neck and back muscles, so characteristic with onset of the acute stage, invariably disappears without evidence of muscle weakness or paralysis.

12. There was no correlation between the degree of spasm and the incidence of muscle weakness or paralysis.

SUMMARY

From action current records made in relation to the study of the neuromuscular reactions of patients in the acute stage of infantile paralysis we conclude that the spine sign is a gross manifestation of the lesser degree of spasm recorded in muscles of normal and sub-normal strength.

Fig. 14.—Patient with infantile paralysis. A, action current record of maximal voluntary contraction of left gastrocnemius taken Dec. 4, 1941. B, action current record of maximal voluntary contraction of left gastrocnemius muscle taken March 10, 1942.

In association with the latter, certain functional abnormalities other than muscle weakness were observed in the lower reflex arc. They could be most readily explained in terms of a dysfunction at/or proximal

to the dendrites or cell body of the lower motor neuron. This dysfunction resulted in a partial isolation of the lower motor neuron from the inhibition normally induced by other levels through long and short neural pathways. The degree of lower reflex arc isolation thus established and the degree of viability remaining in the

Fig. 15.—Same patient as in figure 14. A, action current record of reaction to stretch (stretch reflex) of left gastrocnemius muscle taken Dec. 4, 1941. B, action current record of reaction to stretch (stretch reflex) of left gastrocnemius muscle taken March 10, 1942.

lower motor neurons therefore determined the amount of muscle spasm in each instance.

Without the involvement of levels proximal to the lower motor neuron there would be no spasm, but the muscle could be either weak or normal, dependent on the number of normal motor neurons innervating the muscle.

If all motor neurons failed to be stimulated by the stretch reflex there would be no reaction to the stretch reflex even though relationships proximal to the dendrites were normal.

Spasticity and weakening are two separate phenomena, each dependent on specific disturbances of functions of the anterior horn cells.¹⁶

There was every indication that spasm ran its course like other clinical manifestations of the disease.

The relationship between muscle tenderness and muscle spasm has not been clarified by the work thus far done. As in the past, we should continue to differentiate between pain and hyperesthesia from discomfort due to muscle soreness.

We have emphasized the clinical phenomena and the electromyographic evidence which indicates that muscle spasm does not initiate the development of muscle weakness.

Racial Theory.—The assumption that blood is transmitted at birth from parents to progeny and is inherent in the clan or race from the very origin of the racial stock was and is the cause of the blood feuds and wars among clans, tribes and nations and still remains the basis of strife between different nationalities. The racial theory recently revived by Hitler in Germany is reminiscent of the primitive fantastic idea that the blood of a people is inherited from the very first progenitor of that people, or race, and that the blood of certain peoples contains higher spiritual powers than that of neighboring peoples. The conclusion is drawn that the blood of mythological Roman heroes still flows in the veins of the modern Italians, and that the mythical blood of Wotan still circulates in the vessels of the twentieth century Nazis.—Gordon, Benjamin Lee: *The Romance of Medicine*, Philadelphia, F. A. Davis Company, 1944.

Clinical Notes, Suggestions and New Instruments

BANTI'S SYNDROME APPARENTLY DUE TO INFECTION WITH SCHISTOSOMA MANSONI

THOMAS P. ALMY, M.D., AND J. G. MASON HARPER,
NEW YORK

Infection with the blood fluke *Schistosoma mansoni* is a highly prevalent disease in Africa, in the northern parts of South America and in the West Indies as far north as Puerto Rico. In the continents of Europe and Asia there is only one small focus, about the city of Aden, Arabia. The disease has apparently never been acquired on the North American continent (fig 1).

The sharp limits of geographic distribution of the disease are due in part to the complicated life cycle of this flatworm, which requires one of a number of species of snail (of the genera *Planorbis* and *Australorbis*) as intermediate host. After development within the snail, the schistosome emerges as a larva, the cercaria, which swims freely near the surface of fresh water streams and ponds and there is capable of penetrating human skin.

Within the human host the growing worms make an extended migration through the blood vessels before reaching their definitive site. They pass in succession through the systemic veins, the right atrium and ventricle, the pulmonary capillaries and the left atrium and ventricle, to be distributed widely in the systemic circulation. Those which reach the mesenteric capillaries pass through into the portal vein, where they reach maturity, mate and then migrate backward in the portal system to reach the venules in the mucosa and submucosa of the colon. This migration is usually not attended by symptoms. When, however, the gravid female worm deposits her eggs in minute venules just beneath the mucosa of the colon, the eggs induce local necrosis, usually with slight hemorrhage, production of small ulcers and symptoms suggestive of mild dysentery. Over a period of many years, during which the disease is clinically silent, a considerable number of ova may be swept by the portal current to the liver, where each produces a minute area of necrosis. These miliary necroses are healed by scarring and the nearly typical portal cirrhosis may be complicated by splenomegaly, ascites and other sequelae of portal hypertension.

In the case herein described, the typical features of Banti's syndrome were apparently due to infection with *S. mansoni*. A number of such cases in former residents of the endemic areas have been previously identified in the United States by Price¹ and others; yet in the records of our large urban hospital, covering thirty years (1914-1944) and nearly 350,000 admissions, this is the first case of schistosomiasis. It is reported not only for its relative rarity but also as an illustration of the influence of geography on clinical diagnosis.

REPORT OF CASE

This 44 year old Mohammedan Arab was born near Aden, Arabia, and lived there until 1914, when at the age of 15 he

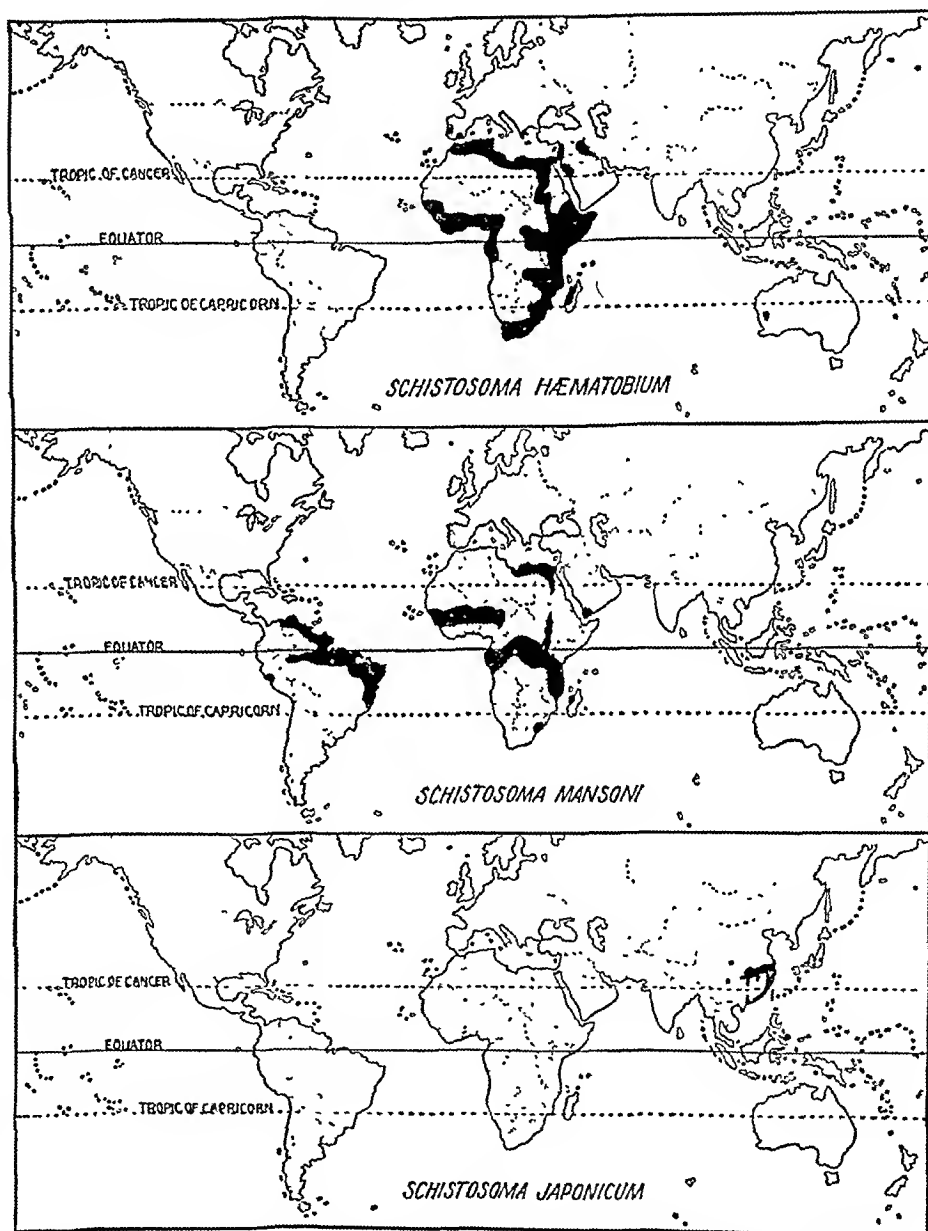

FIG. 1.—The world distribution of schistosomiasis (from Belding Textbook of Clinical Parasitology, New York: D. Appleton Century Company).

¹ From the Department of Medicine of New York Hospital and Cornell University Medical College.

Dr. Henry E. Meloney, professor of preventive medicine at New York University, gave helpful suggestions as to diagnosis and therapy. Dr. J. T. Culbertson, assistant professor of bacteriology at the Columbia University College of Physicians and Surgeons, supplied antigen for skin testing.

joined the British navy. For five years he traveled widely in the navy and then in the merchant marine, only once going ashore, for a few hours, in an area infected with *S. mansoni*. This was at an Egyptian port, and he had no contact with fresh water while ashore. He landed at Portland, Maine, in 1919 and has remained in the United States since that time.

1. Price A. S. Schistosomiasis (*S. Mansoni*). A Report of 7 Imported Cases. Rev. Gastroenterol. 6: 215, 1939.

The patient recalled a few episodes of diarrhea with bloody stools at about 14 years of age but remembered no notable pruritus, severe cough or hemoptysis. He had enjoyed excellent health until his present illness. His diet included moderate amounts of fruits and vegetables and small amounts of lean

Fig. 2.—Patient's protuberant abdomen, with transverse groove.

meat. He abstained from alcohol. Two years before admission, when a left inguinal hernioplasty was performed, his spleen was found to be enlarged.

The patient had suffered from a chronic dry cough during the winter for many years. Ten months before admission,

Fig. 3.—Outline of liver and spleen.

following a fracture of two ribs in a fall downstairs, he had persistent, more severe coughing, and mild malaise. Three months before admission he became conscious of increasing weakness and weight loss. One month later he first noted heaviness and swelling of the abdomen and swelling of the legs. He became decidedly dyspneic on mild exertion, having to stop

after climbing seven steps, but had no orthopnea. He had no nausea or vomiting, no hematemesis or melena, no notable abdominal pain and no jaundice.

The patient was dark skinned and moderately well nourished. His abdomen was protuberant and he was coughing, but he could lie flat without distress. His mucous membranes were pale. The scleras were slightly yellow and displayed bilateral pingueculae. The diaphragms were high, and there were fine moist inspiratory rales at both bases. The heart was not enlarged and was without murmurs. The sharp edge of a hard, nontender liver was felt 7 cm. below the costal margin in the midclavicular line, and the hard, rounded tip of the spleen was felt at the level of the umbilicus. A shallow transverse groove about 3 cm. wide extended across the abdomen at the level of the umbilicus (figs. 2 and 3). There was no fluid. A reducible inguinal hernia was present under an oblique left lower quadrant scar. There was moderate edema of both ankles and pretibial areas.

Examination of the urine showed rare red blood cells and leukocytes. Blood examination revealed hemoglobin 5.2 Gm., erythrocytes 3,600,000, hematocrit 26 per cent, platelets 90,000, reticulocytes 0.5 per cent and leukocytes 4,000 with 6 per cent lymphocytes, 10 per cent monocytes, 12 per cent eosinophils, 2 per cent basophils, 53 per cent mature polymorphonuclears and 17 per cent band forms. The serum protein level was 6.3 to 7.4 per cent with globulin content 3.2 to 4.1 per cent. The cephalin

Fig. 4.—Ovum of *S. mansoni* (from Giffen in Belding: Textbook of Clinical Parasitology, New York, D. Appleton-Century Company).

flocculation test was 3 plus and the flocculation test for syphilis (Mazzini) was 3 plus, with the Wassermann reaction negative. The icterus index was 6.0. The prothrombin level (Werner, Brinkhous and Smith method) was 53 per cent and rose only to 55 per cent after 2 mg. of menadione was injected intramuscularly. Chest x-ray and barium enema were negative. A gastrointestinal series disclosed large esophageal varices. The stools were uniformly positive for occult blood.

The patient was given iron sulfate, elixir of choline chloride, daily intramuscular injections of crude liver extract and a high protein, high carbohydrate diet with supplements of crystalline vitamins. After three weeks his hemoglobin had risen to 11.9 Gm. and his erythrocyte count to 4,900,000, his leukocyte count was unchanged and his eosinophil percentage had fallen to 4. Ankle edema was no longer present and he felt much stronger.

At this time it was suspected that he might have schistosomiasis, and a skin test was performed with antigen obtained from the frog lung fluke (*Pneumoneces medioplexus*).² This was moderately positive. Repeated stool examinations were made by various methods of concentration. On the eleventh such examination, in which the acetic acid-ether method of de Rivas³

2. Culbertson, J. T., and Rose, H. M.: Skin Tests in Schistosomiasis with Antigen from *Pneumoneces Medioplexus*, *Am. J. Hyg.* 36: 311, 1942.
3. de Rivas, D.: An Efficient and Rapid Method of Concentration for the Detection of Ova and Cysts of Intestinal Parasites, *Am. J. Trop. Med.* 8: 63, 1928.

was used, an ovum of *Schistosoma mansoni* was found (fig. 4). This observation was repeated in six different preparations from two stools, and the identity of the ova was confirmed by Dr. Ralph W. Nauss, parasitologist to the New York Hospital.

The patient was then treated with fuaadin in 6.3 per cent solution, given daily by muscle in dosage increasing from 0.8 cc. to 5 cc. and then maintained at this level for nine additional injections given every other day—a total of 62.6 cc. There were no toxic manifestations and no further change in the symptoms and signs of hepatic disease, or in the blood count, except for a secondary rise of the eosinophil percentage to 25 at the end of treatment. The cephalin flocculation reaction during treatment was 1 plus.

When the patient was last seen, ten weeks after the conclusion of treatment, strength and exercise tolerance had improved. He had climbed ten flights of stairs slowly without stopping. Although ankle edema had disappeared, he had maintained his weight. The liver and spleen were not changed in size. The blood count had remained the same except for a secondary fall of the eosinophil percentage to 7.

COMMENT

In retrospect, there were several reasons for suspecting the parasitic origin of Banti's syndrome in this patient. He had spent the earlier years of his life in a recognized endemic focus of schistosomiasis mansoni. His abdomen presented a shallow transverse groove similar to that described by Faust and Meleny⁴ in advanced cases of schistosomiasis japonica. It is thought by them to indicate adhesions of the omentum and mesentery to the abdominal wall, with contraction of scar tissue in these adherent structures. To our knowledge this clinical feature has not previously been described in schistosomiasis mansoni. The patient's blood showed an eosinophilia, which is rarely seen in Banti's syndrome of nonparasitic origin. The diagnosis was strongly suggested by a positive skin reaction to a trematode antigen but could not be considered as established until the ova of *S. mansoni*, after a prolonged search, were identified in the stool.

The chronicity of this patient's disease was of special interest. It is probable that he was infected at his place of birth, which he left thirty years ago. It is certain that he was infected more than twenty-five years ago, since which time he has lived in the United States.

In the late stage of schistosomiasis which this patient illustrates, treatment with anthelmintic drugs is risky. It is widely held that in the presence of advanced hepatic damage antimony and potassium tartrate is contraindicated and fuaadin must be used with caution. Furthermore, the benefit to the patient of such treatment is small, because most of the clinical phenomena are due to irreversible scarring of the liver. The early stages of the disease, those characterized clinically by skin rashes, asthmatic states and protean gastrointestinal symptoms, present greater therapeutic opportunities. In such cases there is usually less difficulty in finding the ova in the stools, but their presence must first be suspected. The variable symptoms and physical signs do not often present a clue and the eosinophilia is inconstant, but any patient may be logically suspected of having schistosomiasis who has exposed himself to fresh water in one of the sharply limited endemic foci of the disease. It is therefore suggested that the first consideration in diagnosis is a geographic one, the fact of exposure to the disease. In the near future, with many Americans returning from endemic foci of schistosomiasis, such thinking may become important in clinical diagnosis.

SUMMARY

Banti's syndrome occurring in a 44 year old Arab was found to be due to schistosomiasis mansoni, although the patient must have acquired this infection more than twenty-five years before the onset of symptoms. The patient was treated with fuaadin, with indeterminate results. As it provides a valuable clue in the clinical diagnosis of schistosomiasis mansoni, stress is laid on the limited geographic distribution of endemic foci of this disease.

Council on Physical Medicine

The Council on Physical Medicine has authorized publication of the following report. HOWARD A. CARTER, Secretary.

TELEX NEW "SUPER HEARING AID
(Model #1550)
ACCEPTABLE

Manufacturer: Telex Products Company, Telex Park, Minneapolis.

This is a vacuum tube hearing aid consisting of four midge tubes, a transmitter, a crystal receiver in a flesh colored molded case and a battery unit. Weights and overall dimensions of the various parts of Model #1550 are as follows:

Transmitter, 4 inches by 2¼ inches by ¾ inch, weight with cords 5 ounces.

Receiver, crystal, 1 inch in diameter.

Batteries, weight 11 ounces.

Total weight of the entire instrument is 16 ounces.

Batteries.—Voltages and current drains are as follows:

A battery, 1.5 volts.

Current drain at ½ volume 110 milliamperes.

Current drain at full volume 110 milliamperes.

B battery, 45 volts.

Current drain at ½ volume 1.5 milliamperes.

Current drain at full volume 1.5 milliamperes.

An additional drain of 0.3 milliamperes occurs with loud signal.

Acoustical Gain.—The following data are the average of observations of two trained observers using fitted ear molds seated 5 feet from the loud speaker delivering frequencies of pure sine wave characteristics. (Test made with tone control at "normal white dot position.")

Volume Control Set at	Frequency							
	256	512	1,024	1,448	2,048	2,896	4,096	
½	9	6	8	14	11	10	13	Decibels
¾	15	10	15	19	16	14	18	Decibels

Overall gain for speech 31 decibels. This is an intelligibility speech measurement based on what the patient can understand without the hearing aid and with it.

Physical and Mechanical Features.—The instrument consists of a black plastic molded case of convenient size and pleasing appearance. It is very well made. The electrical assembly has been done in a thoroughly workmanlike manner. There are two controls, one the volume control, a studded disk placed on the top of the instrument. It operates smoothly and easily. A second, the tone control situated on the upper left hand corner of the side, operates in three positions marked by blue, white and red dots. The cord connections are well made and seem to maintain their position without shifting. The battery pack is conventional in type.

Telex Hearing Aid, Model 1550.

Performance.—In this test the instrument submitted performed as represented. At full volume, however, there is definite feedback squeal even with a tight fitting receiver. At full control the instrument performs unusually well. As shown in the graph submitted by the firm, shifts in the low frequency are emphasized very definitely. The booklet of instructions is complete and adequate.

Recommendations.—The aid itself and the descriptive matter which were submitted fulfils the requirements for acceptable hearing aids of the Council on Physical Medicine.

The Council voted to accept the Telex new Super Hearing Aid, Model #1550, for inclusion in its list of accepted devices.

MEDICAL CERTIFICATES AND WAR PRODUCTION

In recent years medical certificates have been required for fuel and food rationing, public health disease prevention programs, food handler control, marriage laws, school regulations and sickness insurance.¹ The good name of the medical profession is sometimes jeopardized by too lenient compliance with appeals for certificates from patients who often have little or no real basis for requesting them. This problem is now especially concerned in present efforts to use limited manpower to its fullest extent in war industries.

Production of munitions would be far from completed even if Germany should capitulate this month. According to War Department announcements, production of heavy trucks, large shells, bombs, rockets, smokeless powder, heavy duty tires, superbombers and large artillery is behind schedule for 1944. These activities must be continued for many months to come if urgent orders from overseas are to be met. The major problem in the production of these critical items is lack of manpower. Lack of labor reserves in many communities, excessive absenteeism and a high rate of labor termination are the controlling factors in producing enough munitions on time. Certain ordnance plants have reported absenteeism amounting to twenty days annually per man² and an annual labor turnover of 100 per cent. Many of these absentees and job terminators can be replaced only with the greatest difficulty.

Many observers believe that the principal underlying cause is the too common attitude that the war is almost over. The feeling of urgency is gone. Liberal disability benefits contribute to these delays. Others who drop out for a few days of hunting or to get in the crops cheerfully extend an unjustified absence and cover up

by alleging illness on return to work. Job quitters likewise are more common than ever because of their understandable desire to obtain more permanent work before present jobs terminate.

Industry, labor organizations, the War Manpower Commission and other interested agencies have instituted an aggressive plan of action to control the ordinary causes of absenteeism and labor turnovers by giving attention to such factors as housing, transportation, shopping facilities, cafeterias, child care and impressing the workers with the urgency of staying on the job.

Illness, both alleged and real, as a frequent cause of absenteeism and work termination is probably the most difficult problem to control by lay agencies. The government and its contracting agents customarily require medical certificates to cover an absenteeism alleged to be illness or a labor termination attributed to reasons of health. The medical profession is then put under pressure by thoughtless persons who see little harm in collecting disability benefits or in obtaining better jobs on pretext of illness. They fail to see the cumulative results of hundreds of thousands of such acts on critical war production.

Responsibility rests squarely on the physician to act as prosecutor, defense attorney and judge before issuing such a certificate. He fails himself, his profession and the war effort if certificates are issued without due cause. The Army³ is prepared to cooperate closely with physicians in industry in order to accumulate facts about alleged illness of an employee and the possible effects of the working environment on the employees' health. Standard practices for the control of health hazards in war industries are available. The medical records of employees and diagnostic services of these plants are generally available to private physicians in troublesome cases and should be utilized fully.⁴

The medical profession is never out of the public eye. The ability of any group of workers persistently to evade the obligations of their jobs through easy availability of medical certificates must inevitably arouse unfavorable public reaction. The War Participation Committee of the Massachusetts Medical Society has established a system for review of medical certificates in that state⁴ worthy of general consideration. Every physician must assure himself that each medical certificate is exactly what it implies—a certified statement of facts based on careful examination and disinterested judgment.

AIR BORNE TUBERCULOSIS

Following development of Topley's¹ method for the study of herd infections, studies of the experimental epidemiology of tuberculosis were begun in the Henry Phipps Institute at the University of Pennsylvania. In the initial experiment Perla² exposed normal guinea pigs to tuberculous cage mates which had been previously infected intraperitoneally with highly virulent bovine type tubercle bacilli. The exposed guinea pigs readily contracted tuberculosis. This with few exceptions had the characters of an infection that had entered by way of the digestive tract. Involvement of the mesenteric and cervical lymph nodes was conspicuous in necropsies with an occasional tuberculous ulcer of the ileum. The infection was apparently the result of fecal contamination of the food material. After such intraperitoneal inoculation guinea pigs usually begin the elimination of tubercle bacilli in the feces within a week. There is a rapid increase in the number of tubercle bacilli per fecal bolus during the terminal weeks of the disease.

In the same experiments Perla found that out of 16 normal guinea pigs placed in the same room but not in the same cages with tuberculous animals 2 guinea pigs acquired tuberculosis, presumably as a result of air borne contagion. Each of these cases had the characters of a bronchogenic infection, the dominant lesions being in the lungs and tracheobronchial lymph nodes.

A more detailed study of air borne tuberculosis was therefore undertaken. Twenty-seven cages, each containing 2 normal guinea pigs, were evenly distributed and left undisturbed for several months in a large room harboring about 500 experimental animals, many of them tuberculous. Precautions were taken to rule out non-air borne infection. Lurie³ found that none of the guinea pigs thus exposed for a period of six months developed tuberculosis. Of the guinea pigs exposed for periods ranging from six to twelve months, 9.1 per cent developed a typical respiratory tract infection. Among those exposed for from twelve to eighteen months 27.7 per cent developed air borne tuberculosis. The morbidity increased to 35.3 per cent among those exposed for periods ranging from eighteen months to two years. Of the 20 guinea pigs that did not contract the disease by the end of two years only 1, or 5 per cent, was subsequently infected. Apparently under his method of exposure animals that do not develop tuberculosis by the end of twenty-four months have a hereditary or acquired resistance to subsequent infection.

Following the demonstration by Wells⁴ that pure cultures of tubercle bacilli suspended in air can be

killed within three seconds by exposure to ultraviolet light, Lurie⁵ and his associates developed a technic for testing the possibility of preventing natural air borne tuberculosis by ultraviolet rays. Two duplicate rooms were prepared. Each room contained a battery of individual cages for normal rabbits with a parallel group of cages for rabbits previously infected intravenously with highly virulent bovine type tubercle bacilli. These infected rabbits were shedding highly virulent tubercle bacilli in the urine. The two batteries were so placed that the natural air currents of the room were from the infected to the exposed rabbits. In the test room the space between the donor and recipient cages was flooded by ultraviolet light. No lamp was installed in the control room.

The recipients in each room were litter mates of the same highly inbred, genetically uniform rabbits. Three genetic strains were used: a hereditarily highly resistant rabbit family and two families of low hereditary resistance. Every two weeks each of the exposed rabbits was tested for acquired skin sensitivity, and every four weeks it was x-rayed. At the end of fifteen months all surviving exposed animals were killed and carefully examined, guinea pig inoculation being resorted to in case of the least doubt.

In a typical experiment (1942-43 series), 8 hereditarily resistant rabbits and 7 rabbits of the susceptible families were placed in each room. Within six to twelve months all exposed rabbits in the control room had developed a high degree of skin sensitivity. Twelve of the 15 had developed from 2 plus to 4 plus tuberculosis, of which 9 died. In the irradiated room no rabbit developed a positive skin reaction by the end of twelve months. But 1 ultraviolet room rabbit developed a questionable pulmonary lesion. From this lesion tubercle bacilli were isolated by guinea pig test.

Summarizing the results of three years' research, Lurie concludes that under the conditions of their experiments ultraviolet rays of high intensity completely protect all rabbits, whether of high or low natural resistance, from an air borne contagion so severe as to be fatal to the great majority of rabbits of the same genetic constitution if not protected by such radiation. The protected animals do not develop tuberculin sensitivity. With irradiation of low intensity, rabbits of high natural resistance are completely protected from acquiring demonstrable tuberculosis, though they do acquire tuberculin sensitivity. Low intensity irradiation, however, does not protect all rabbits of low natural resistance from acquiring lethal tuberculosis. From these encouraging results Lurie believes that "it is probable that ultraviolet radiation may control air borne contagion of human tuberculosis."

Current Comment

GRADUATE EDUCATION OF PHYSICIAN VETERANS

Elsewhere in this issue, page 709, appears a report on the graduate education of physician veterans which carries information of the greatest importance to all physicians now serving with the armed forces. Preliminary reports on the results of the questionnaire sent by the Committee on Postwar Medical Service to all physicians in the armed forces indicate that the majority of physicians wish graduate education, including short and long courses, in the postwar period. Under existing legislation physicians, like other veterans, are entitled to payment of tuition and also to cost of subsistence when engaged in such courses, subject to limitations which depend on the duration of the service and similar factors. A conference held by representatives of the Committee on Postwar Medical Service with representatives of the Veterans Administration and of the Vocational Rehabilitation and Education Service brought out the facts clearly.

GENERAL MEDICAL COVERAGE FOR INDUSTRIAL EMPLOYEES

Recently in *THE JOURNAL* a series of articles¹ was published describing some of the variations in approach which representative industries have made to the problem of general medical coverage for their member-employees. The Council on Industrial Health, in recognition of this trend, has adopted a statement of policy which should be helpful to physicians and medical societies faced with these developments. This statement, as approved by the Board of Trustees of the American Medical Association, is as follows:

Pressure is being placed on industry by management and by labor to extend the health services for which it is responsible. It has been recognized that industry has certain responsibilities in providing medical care for occupational injuries and diseases. These responsibilities have been extended to include various services in the field of preventive medicine. It is now proposed that industry provide over-all medical care for employees and their dependents, the term medical being used in a broad sense to include diagnosis and treatment in various special fields. The Council on Industrial Health believes that a statement along the following lines bearing the stamp of approval of the American Medical Association will be of assistance to physicians who are now confronted with this situation in many areas:

1. The principles on which medical care plans should be based have been defined by the House of Delegates of the American Medical Association. In developing medical care plans, industry should be in agreement with the local county medical society as to the conformity of such plans with these established principles. Plans of this nature should include provision for health maintenance programs.

2. Because of the essential medical nature of such plans, their policies should be directed and the medical phases should be controlled by the medical departments of industry.

3. The attention of industrial management should be directed to the place of the physician in industrial organization. The expanding importance of health activities in industry demands that the physician be responsible directly to top management and that activities relating to health be centered in and directed through the medical department.

THE DALLAS VENEREAL DISEASE CONTROL PROGRAM

A Venereal Disease Control and Educational Program was organized in Dallas, Texas, in the summer of 1943 at the suggestion of the commanding officers of the armed forces in that area. A report by the Dallas Venereal Disease Educational Committee¹ was issued on July 1, 1944. The Dallas program differs from the Chicago program² in that the Chicago program is a cooperative one in which the United States government, the state of Illinois and the city of Chicago are primarily concerned, whereas the Dallas program was carried out by two local committees, one on venereal disease control and the other on venereal disease education. The report outlines the procedures and describes the results. Pictures by the United States Army Signal Corps show the participation by community agencies and the public in the program. A typical double page spread layout shows a street corner with curb billboard, another billboard at factory gates, posters in a public waiting room, information on the inside of a washroom door, windshield stickers, car cards, a clinic scene, a dinner meeting and informational posters at soda fountains. Stickers were placed in juke boxes and elaborate exhibits displayed in public places. Films were used; these were seen by more than ninety-four thousand persons during the campaign. Fifty thousand water bills were stuffed with folders featuring venereal disease information. An active speakers' bureau, in which forty-four physicians participated, scheduled as high as three and four talks a day. Newspaper space was used to a total of 1,412 inches of paid advertising at a special rate lower than the regular advertising rate. In this program the people of Dallas got to work. The entire expense of the campaign was just over \$3,000, but this does not count the value of volunteer labor or the expense of materials received gratis from official agencies, especially the state health department. Results are indicated as follows: "A recent report by the medical director of the Eighth Service Command showed that the average rate of infection among military personnel for the three month period ending June 1, 1944 was 10.5 cases per week, a drop of more than 80 per cent as compared with the average weekly rate at the beginning of the campaign." A year is a short time in public health history. Doubtless this campaign, if continued, will show even greater results not only in the military but in the civilian population.

MEDICINE AND THE WAR

POSTWAR PLANNING

GRADUATE EDUCATION OF PHYSICIAN VETERANS

Report of the Subcommittee of the Committee on Postwar Medical Service

Dr. Frederick A. Collier, Dr. Walter Palmer and Father Alphonsc M. Schwitalla, three members of the Subcommittee on Postwar Education of Physician Veterans, were accorded interviews with officials of the Veterans Administration on the afternoon of October 16. The other two members of the committee, Dr. Victor Johnson and Lieut. Col. Harold C. Lueh, found it impossible to attend.

The subcommittee called first on Dr. Charles M. Griffith in the office of the Medical Director, Veterans Administration Building, and after an exchange of courtesies was escorted by him to the office of Mr. Harold V. Stirling, Director, Vocational Rehabilitation and Education Service. Dr. Griffith explained that Mr. Stirling was in charge of the administration of title II of education of veterans of Public Law 346, 78th Congress, known as the "Servicemen's Readjustment Act of 1944" (the G. I. bill), and Public Law 16 was Mr. Stirling's responsibility.

Dr. Griffith explained that after the committee's interview with Mr. Stirling to learn from him the present status of Public Law 346 and its application to the physician veterans, he would discuss with the committee further the content and administration of the educational program itself which the Veterans Administration has projected or intends to project for the returning physicians.

I. ELIGIBILITY OF INSTITUTIONS

Mr. Stirling suggested that the committee discuss first the eligibility of institutions for recognition as educational centers in which veteran physicians might receive such educational benefits as are provided for under the law. He turned to section 400, part VIII, paragraph 4, and called attention to the fact that it is incumbent upon the administrator to

secure from the appropriate agency of each state a list of the educational and training institutions (including industrial establishments), within such jurisdiction, which are qualified and equipped to furnish education or training (including apprenticeship and refresher or retraining), which institutions, together with such additional ones as may be recognized and approved by the administrator, shall be deemed qualified and approved to furnish education or training to such persons as shall enroll under this part.

Mr. Stirling noted that the law distinguishes between institutions (giving training) "and establishments furnishing apprentice training on the job" (see paragraph 5). The institutions in which discharged physicians would receive their postdemobilization education, such as the hospitals, will, of course, qualify as institutions and will not be considered merely as "establishments furnishing apprentice training on the job."

To qualify as "institutions," the schools of medicine and the hospitals in which the returning physician will be further educated will have to appear by name on a list of educational and training institutions furnished by the appropriate agency of each state to the administrator. The administrator is given authority by the law to "recognize and approve" institutions on his own initiative. Obviously, however, the administrator will not undertake as a rule an approving or accrediting program and will rely on such lists as are furnished him by the appropriate agency of each state.

As far as medical education is concerned, there is very little difficulty about the schools of medicine, since most, if not all, of the states would readily submit the names of schools recognized by the Council on Medical Education and Hospitals of

the American Medical Association. Much greater difficulty, however, will be found in supplying to the administrator a list of the recognized and approved hospitals, and a decision will have to be made concerning the list which all will agree will be the proper list to submit to the administrator. Mr. Stirling is of the opinion that it might be well if the administrator's office send to the governors of the various states such lists of institutions, schools and hospitals as are recognized and approved by appropriate agencies with the request to the governor to indicate his approval or disapproval of these lists as appropriate educational centers for the further education of the physician veterans under the program. Naturally, there are other outstanding problems concerning the eligibility of institutions which will need further discussion.

The important conclusion, however, is that in Mr. Stirling's opinion the schools and hospitals can be regarded as institutions within the intent and scope of the Servicemen's Readjustment Act of 1944, provided such institutions qualify under the provisions of paragraph 4, part VIII, title II, Public Law 346.

II. ELIGIBILITY OF INDIVIDUALS

"Any person who served in the active military or naval service on or after Sept. 16, 1940 and prior to the termination of the present war and who shall have been discharged . . . and whose education or training was impeded, delayed, interrupted or interfered with by reason of his entrance into the service . . . and who either shall have served ninety days or more . . . shall be eligible for and entitled to receive education or training under this part" (section 400, part VIII, paragraph 1). A number of provisions and limitations are included in the unquoted section of this paragraph but, in general, the substance of the provision is accurately given. Discharged servicemen under 25 years of age at the time they entered the service are assumed to have had their education impeded or delayed, while those 25 years of age or over at the time they entered the service will be expected to supply evidence that such a delay or obstacle to their education occurred.

With reference to the section just quoted, Mr. Stirling was of the opinion that any physician who is now in any of the branches of the service and has been on active duty for more than ninety days will be eligible for any of the benefits provided by the law. Even those who are more than 25 years old and desire refresher or other courses will no doubt be considered eligible even though they may have entered the Army at a time when their education might have been assumed as completed, since the law in providing refresher and retraining courses is naturally to be interpreted in a liberal spirit.

Any person who has been in active service for three months will be entitled to a period of one year of education or for such lesser time "as may be required for the course of instruction chosen by him." Those servicemen who have been in the service for more than the minimum period of three months may receive additional periods of education or training, the period "not to exceed the time such person was in active service on or after Sept. 16, 1940 and before the termination of the war." Periods during which a serviceman was receiving his education under the auspices of the Army or Navy while on active duty cannot be counted toward time credit for a prolongation of the educational period. The committee asked Mr. Stirling to apply this to the ordinary clinical residency. It was explained to him that the residencies in our hospitals, for example, were one, two or three years or more in length. He replied that:

Those in service three months are entitled to one year further education;

Those in service twelve months are entitled to two years further education;

Those in service twenty-four months are entitled to three years further education.

1. The problem of the state approved but not nationally approved schools of medicine was not touched on in this conference.

Intermediate periods of service entitle the serviceman to intermediately long periods of education, thus if a serviceman has served six months he is entitled to eighteen months of further education.

III TUITION AND FEE BENEFITS

The law provides that the administrator shall pay to the educational or training institution the tuition costs and fees as are customarily charged and may also pay for books, supplies and equipment and other necessary expenses, provided the payments with respect to any one person should not exceed \$500 for an ordinary school year. These payments are not to be paid to "establishments furnishing apprentice training on the job." The law provides that if the institution has no established tuition fee or if the administrator deems the established tuition fee to be inadequate compensation the administrator is authorized to provide for the payment. Again, however, with the \$500 ordinary school year limitation.

Applying these provisions of the law to the case of residencies in our hospitals and courses in our universities for our physician veterans, Mr. Stirling was of the opinion that there would be no difficulty about the payment of tuition and fees by the administrator for those physician veterans who elect courses in schools of medicine or for those who elect clinical courses in university hospitals where a formal program has been inaugurated. He was also of the opinion however that provided the hospital can be certified to the administrator by the appropriate state agency as a competent educational and training institution, the administrator may fix the tuition to be paid to such an institution under the provisions of the law (see last sentence section 400, title VIII, paragraph 5).

The arrangements heretofore in use in hospitals were explained to Mr. Stirling, it being pointed out that the hospital generally speaking not only did not charge tuition but actually offered the resident a stipend. He replied by saying that in his opinion if the hospital is certified as a bona fide educational institution the tuition for the physician veterans can be paid to that hospital even though the hospital still continues to pay a stipend to the veteran.

IV SUBSISTENCE BENEFITS

The law provides further that on application to the administrator the person taking courses shall be paid a subsistence allowance of \$50 per month if without a dependent or dependents or \$75 per month if he has a dependent or dependents.

This provision again Mr. Stirling believes, is applicable to the physician veterans who choose to take courses in medical schools or hospitals. Mr. Stirling is of the opinion, furthermore that the subsistence benefit may be paid the physician veteran even if he receives a stipend from the hospital, since in some cases the physician veteran will undoubtedly live outside the hospital and in many cases there will be a noticeable disproportion between the stipend paid by the hospitals and the salary level of the physician veteran before his discharge. It was pointed out, furthermore, that the subsistence benefit includes "regular holidays and leave not exceeding thirty days in a calendar year." There may still be some question whether the provisions of the law pertaining to attendance in courses on a part time basis and a corresponding part compensation for productive labor are applicable here but there seems no reason to anticipate an adverse ruling on this point. Furthermore, it should be noted that the administration has thus far defined a school year as thirty weeks for the purpose of administering the law, hence the tuition allowance of \$500 maximum can be made payable to the institution every thirty weeks if that is the interpretation and regulation under which the educational institution is operating. The subsistence benefit is not affected by the length of the school year.

V STATUS OF THE VETERANS ADMINISTRATION PHYSICIANS

The provisions of the Readjustment Act as summarized apply of course, to all institutions in which the physician veterans will expect to take courses, hence the committee asked Dr. Griffith whether in case the Veterans Administration opens its own hospitals to the physician veterans for refresher and retraining courses and for residencies, just what the status of these physicians would be.

Dr. Griffith explained that this is one of the outstanding problems which the Veterans Administration must face. At the present time the Veterans Administration physicians under a civil service status are full time appointees and at present there is no provision in the organization for residents. A graduate of a school of medicine who has had a good education, if appointed, enters the Veterans Service at a salary of \$3,200. After about eighteen months his salary is approximately \$3,800 while after ten to fifteen years he may reach a base salary of \$6,400. Clearly, the physician veterans if appointed to such positions would be in a particularly fortunate position at least with reference to salaries but obviously such an arrangement is not the one which is contemplated by the Servicemen's Readjustment Act. Just how this problem will be solved if the facilities of the Veterans Administration are offered for this educational program is not clear at the present time. A medical corps within the Veterans Administration would obviously solve the problem.

It is expected that within approximately five years the Veterans Administration will have 300,000 beds in about 150 institutions. At present the administration has about 1,800 physicians, approximately one fifth of whom are at the higher salary levels. This will give some indication of what might be expected in the future, but the Vocational Rehabilitation Program of the Veterans Administration will require many more physicians than would be indicated by the present physician to patient ratio. It would seem briefly, that it is highly desirable to establish an educational program within the Veterans Administration for the physician veterans so that these veterans may have the benefit of the unquestionably large and desirable facilities of the veterans' hospitals and secondly that the administration must make provision for a much larger physician personnel.

VI MEDICAL SERVICES OF THE VETERANS ADMINISTRATION

The committee was given the benefit of a further interview with Dr. Charles M. Griffith, Medical Director, and with Col. Hugo Mella, M. C., Assistant Medical Director, in charge of Postgraduate Instruction and Medical Research. Dr. Griffith explained the structure of the Veterans Administration emphasizing the extent and variety of the medical responsibilities of the administration. The medical director is responsible to the administrator through an assistant administrator. He has a number of assistant medical directors (at present five) who are in charge of various divisions namely general medicine and surgery, neuropsychiatry, outpatient and authorization tuberculosis and, lastly, postgraduate instruction and medical research. There are a medical executive officer and a medical consultant. The only medical activity of the administration which does not fall within the responsibility of the medical director is the medicolegal activity, namely the activity of physicians on various boards dealing with claims, adjustments and insurance.

Dr. Griffith and Colonel Mella then went on to speak of the various kinds of physician veterans in whom the Veterans Administration is interested. The first class is the discharged physician who qualifies for further education under the G. I. bill and who is adequately taken care of. The second group is the group of those who would like to qualify for an educational program in the Veterans Administration itself. The status of this group is not clear at the present time, since provisions must still be made for them. A third group of physicians might be those who would be discharged on the basis of physical disabilities and for whom both educational and other provisions will have to be made. If it was possible for the Veterans Administration to organize its own board and its own medical corps, many of the present difficulties with reference to medical care within the Veterans Administration could be promptly removed. At present the Veterans Administration has had assigned to it a number of physicians by the Surgeon General. Colonel Mella stated, after being asked that for the next two years he estimates that in the veterans' hospitals there should be place for approximately 250 residents. He estimates, furthermore, that 50 per cent of these could be employed in surgical residencies, 35 per cent in psychiatric and internal medicine resi-

dencies and 15 per cent in tuberculosis residencies. He called attention to the great difficulty under which the administration labors in developing an educational program arising from the fact that neither psychiatric nor tuberculosis hospitals have thus far been approved for residencies. By whom and when will such approval take place and what agency will undertake the definition of staff membership qualifications?

It is obvious that the Veterans Administration has given considerable thought to the organization and content of an educational program for physician veterans. Colonel Mella is studying the outline for graduate instruction in surgery as given to him by the College of Surgeons. He and his assistants are planning, moreover, to organize an appropriate committee in each of the

veterans' hospitals in which residents are to be instructed which will assume responsibility for the educational program, the committee to consist of the chief medical officer, the clinical director and the chiefs of the various services. The administrator has recently approved functional charts of organization for the various classes of facilities of the Veterans Administration, and, with such clear definitions as have been given, it should be a relatively simple matter to integrate with the existing functions the further function of education for our returning physician veterans.

FREDERICK A. COLLIER, M.D., Chairman.
WALTER PALMER, M.D.
ALPHONSE M. SCHWITALLA, S.J., Secretary.

ARMY

MEDICAL FIELD SERVICE SCHOOL AT CARLISLE BARRACKS

When a young man is enrolled in the medical department of the Army he is likely to be sent in the vast majority of cases to the Medical Field Service School at Carlisle Barracks, Pennsylvania. The school is located in Cumberland County at the foot of the Appalachian Mountains. It is about 18 miles from Harrisburg. The primary purpose of this school is instruction and training of officers of the medical department—essentially what is called indoctrination. The needs of war have brought about a condensation of the usual five months course to a six weeks period. In this time the student officer is instructed in tactics, the operation of medical units, preventive medicine, field sanitation and the application of medicine and surgery in the field. Included are practical demonstrations and participation in maneuvers. An officer candidate school for enlisted men of the medical department is carried on simultaneously.

Physical conditioning is an important part of the work and is intended to develop physical stamina, agility and coordination. This involves the usual marching, physical drill and the handling of litters carrying wounded. One area is set apart for actual demonstration of field sanitation. This area occupies 8 acres of ground. Here are shown all the different techniques for disposing of kitchen waste and human waste, for the control of lice, flies, mosquitoes and other insects, rat proofing, the preparation of water for use in the field, the disposal of sewage, the setting up of baths and many other sanitary measures. In the course of this work many new processes have been developed and are widely used in our armed forces.

In the mountain area closely associated with Carlisle Barracks, about 7 miles from the post, the medical officer learns how to read maps, set up medical installations for the transportation of the wounded and perform actually in the field many of the life saving procedures that he will have to do once he is in active service at the front. Furthermore, there is an infiltration course used to condition students mentally to the conditions of combat. Here the student gets out of a trench, crawls 80 yards, negotiates barbed wire obstacles, enters other trenches, and this with machine guns firing ammunition 36 inches overhead.

MEDICAL EQUIPMENT LABORATORY

The Medical Department Equipment Laboratory was established in 1920 by the Surgeon General of the U. S. Army and represents at this time one of the most fascinating museums of medical equipment to be found anywhere. Probably it is the only institution of its kind in the world. Here the visitors can see complete outfits of medical supplies for the operating room, the laboratory and the x-ray unit of the Japanese, Italian, German, French and other armies. Here are experiments in the development of light weight litters, operating units to be used in the field, motorized medical devices and innumerable other forms of apparatus. Here are models of ambulance trains and ambulance ships going back to the time of the Civil War and coming up to the latest of the devices available today. The dental equipment parallels that of medicine. When a need occurs anywhere among our troops in the air, on land or on the sea, a message sent to the Medical Department Equipment Laboratory puts the investigators to work and in the vast majority of instances they have been able to meet every request.

showing ingenuity that taxes the imagination. This laboratory is under the direction of Col. E. D. Quinnell, and any physician who has an opportunity to visit it and to study its content under the tutelage of Colonel Quinnell will be exceedingly well rewarded for his time and interest.

The textbook of Carlisle Barracks is the Instructors' Guide, a comprehensive work on the service of the medical department in war, written especially for the condensed course now being given. Here are all the details of defense against chemical warfare, mechanized warfare, air and parachute attack, land to land combat and what not. The significance of this instruction and training for the good of the nation and for the health and fitness of our troops is so great that one may anticipate a time in the postwar period when the six weeks condensed course may well be part of every medical curriculum.

NONCOMBAT DUTY TO SOLE SURVIVING SON IF TWO OR MORE BROTHERS HAVE BEEN KILLED

In recognition of the sacrifice and contribution made by a family which has lost two or more sons and has only one surviving, the War Department has approved a policy of returning to or retaining in the continental United States the sole surviving son of a family in cases in which two or more sons have been lost, except when the surviving son is engaged in nonhazardous duty overseas.

Sympathetic consideration will be given to every application in cases of families who have lost two or more sons and have only one surviving for return of the survivor to this country for duty here or for discharge from the Army, if the circumstances warrant. However, each case will be decided on its individual merits. In all cases of extreme hardship arising from family circumstances the Army has in the past cooperated to provide relief from active duty or discharge if the complaint has been found to have merit on investigation. The plan of removing men from the hazards of combat activity is an extension of this policy.

HOSPITAL NAMED IN HONOR OF COLONEL MADIGAN

The Madigan General Hospital, Fort Lewis, Washington, has been named in honor of the late Col. Patrick Sarsfield Madigan for his long and faithful service in the Army Medical Corps. At the time of Dr. Madigan's death in May of this year he was chief surgeon at Fort Belvoir, Virginia, Station Hospital. He graduated from Georgetown University School of Medicine, Washington, D. C., in 1912. Dr. Madigan began his army service in 1917, entering the Medical Corps and serving during the last war in France with the 7th Division. He was stationed in the Philippine Islands for two years and served four years in the Panama Canal Zone. In 1940 he was appointed medical adviser to the Surgeon General and the Adjutant General of the Army. Before going to Fort Belvoir in February he was commanding officer of Camp Lee, Virginia, Station Hospital. Col. A. P. Clark is commanding officer at the Madigan General Hospital.

Capt. Richard A. Twyman, formerly of Rochester, Minn., discovered that waxed paper from the wrappers of cigaret cartons can be used for surgical dressings when the usual nonadherent substances are unavailable. Holes are punched at quarter-inch intervals to permit drainage and irrigation. The waxed papers are washed with soap and water, placed in a shallow pan, wrapped like other surgical dressings and then sterilized in the usual manner. Dr. Twyman graduated from Northwestern University Medical School, Chicago, in 1938 and entered the service June 19, 1943.

ORGANIZATION SECTION

Official Notes

CHANGE 1945 ANNUAL MEETING PLACE

The House of Delegates of the American Medical Association at the annual session held in 1942 selected New York City as the place of meeting for the 1945 annual session. Certain preliminary arrangements were completed, but investigations recently made in New York clearly indicate that the necessary facilities will not be available in that city in 1945 because of conditions created by the war emergency. It is with regret that it is necessary to make the announcement that the annual session scheduled for New York, June 11 to 15, 1945, will have to be held in some other city where adequate facilities will be available. Under the direction of the Board of Trustees necessary investigations are now in progress and definite announcement as to the place of meeting for 1945 will be made through the columns of THE JOURNAL at the earliest possible time.

ANNUAL CONFERENCE OF STATE SECRETARIES AND EDITORS

The Annual Conference of Secretaries and Editors of Constituent State Medical Associations will be held at the offices of the Association in Chicago on November 17 and 18. The program will be as follows.

FRIDAY, NOVEMBER 17, 10 A. M.

Call to Order James R. Bloss, Chairman of the Board of Trustees of the American Medical Association
Address Herman L. Kretschmer, President of the American Medical Association
The Functions and Operations of the Bureau of Information Lieut. Col. Harold C. Lueth, Army Medical Corps Liaison Office
The Council on Medical Service and Public Relations John H. Fitzgibbon, Chairman of the Council
12:30 p. m. LUNCHEON

FRIDAY, NOVEMBER 17, 2 P. M.

Address Roger I. Lee, President Elect of the American Medical Association
The EMIC Program E. D. Phiss, State University of Iowa College of Medicine, and Thurman B. Rice, State Health Officer of Indiana
Medical Service Plans Robert E. S. Young, Member of Medical Service Committee of Ohio State Medical Association

FRIDAY, NOVEMBER 17, 6:30 P. M.

DINNER MEETING OF EDITORS OF STATE MEDICAL JOURNALS
PALMER HOUSE, ROOM 14 CLUB FLOOR
W. R. Brooksher, Editor of the *Journal of the Arkansas Medical Society*, presiding
Our State Journals as Molders of Opinion Herman M. Jahn, Editor of the *Nebraska State Medical Journal*
Attitude of State Medical Journals Toward Political and Social Trends That May Affect Medical Affairs Creighton Barker, Secretary of the Connecticut State Medical Society
Our State Journals as News Services E. M. Shanklin, Editor of the *Journal of the Indiana State Medical Association*

SATURDAY, NOVEMBER 18, 9:30 A. M.

Medical Attitudes, Opportunities and Responsibilities in a National Fitness Program J. W. Wilce, Ohio State University and Member of Official Group of National Committee on Physical Fitness
Radio Broadcasting by Medical Professors A. S. Brunk, President of the Michigan State Medical Society

COUNCIL ON MEDICAL SERVICE WASHINGTON OFFICE

The Washington Bureau of the Council on Medical Service is preparing a list of state association officers and the names of members designated to cooperate with it in the winter's work. The list is about complete, only a few states remaining to be heard from.

The director, Dr. Joseph S. Lawrence, has met with the county legislative chairmen of Indiana at a conference held in

Indianapolis and also with the County Secretaries' Association of Wisconsin at its annual meeting.

The council has had the first of its regional meetings held Sunday, October 29, in Cincinnati. Four states—Ohio, Indiana, Kentucky and West Virginia—composed the region and more than eighty physicians were in attendance. Dr. Edward J. McCormick, a member of the Council, presided, assisted by the three trustees, Drs. Bloss, Sensemich and Henderson, who reside in this district. The two subjects that commanded the most interest were the Council's program and the plans for prepayment insurance. The next regional conference will be held in Washington on December 6 and a third is scheduled for St. Paul on December 10.

Washington Letter

(From a Special Correspondent*)

Nov. 6, 1944

Action Promised on Capital Hospital Center Bill

Despite authorized extensions to local hospitals, efforts will be pressed immediately after the November 7 election to pass the bill to establish a 1,500 bed hospital center in the District of Columbia. Senator Millard E. Tydings (Democrat, Maryland) heads a special subcommittee of the Senate District Committee, which was created to study the measure and hold public hearings on it. He sponsored the bill in the Senate and says that every effort will be made to enact it. A companion bill was introduced in the House by Representative Thomas D'Alesandro (Democrat, Maryland) and is pending. The federal government would bear the entire cost of the proposed medical center. It would be operated on a nonprofit basis by participating private hospitals, with Emergency and Garfield Hospitals forming the nucleus.

Senator Tydings said that the cost of the center was estimated at between \$5,000,000 and \$7,500,000. The center would be equipped with the most modern scientific devices and staffed with the best medical personnel available. The Senate bill has been given the first position on the Senate District Committee calendar, according to Senator Theodore G. Bilbo (Democrat, Mississippi), chairman.

Robert H. Felix New Mental Hygiene Chief, Mental Hygiene Division, U. S. P. H. S.

Appointment of Dr. Robert H. Felix as medical director in charge of the Mental Hygiene Division in the Bureau of Medical Services, U. S. Public Health Service, has been announced by Dr. Thomas Parran, Surgeon General. Dr. Felix replaces Dr. Lawrence Kolb, who retired October 31. A well balanced program of the advancement of mental health in the United States was described by Dr. Felix as his first effort on taking over his new post. He cited present needs for expansion of research and a nationwide extension of psychiatric services to apply the findings of research to the psychic problems of people. Dr. Felix was borne in Downs, Ky., May 29, 1904, received his degree in medicine at the University of Colorado in 1930 and returned at the Colorado General Hospital in Denver. He was granted a two year fellowship by the Commonwealth Fund and took his postgraduate training at the Colorado Psychiatric Hospital under Dr. Franklin R. Ebaugh. He was commissioned in the regular corps of the Public Health Service in August 1933 and had a varied experience in the service. He developed and operated a mental hygiene service for the Coast Guard at New London, Conn., with the advent of war. He is a Fellow of the American Medical Association, the American College of Physicians and the American Psychiatric Association, a member of the Association of Military Surgeons and the Southern Psychiatric Association and a past president of the Kentucky Psychiatric Association.

Toxicity of DDT Described by Dr. Paul A. Neal

In spite of its inherent toxicity, DDT in the desired insecticidal concentrations in the air is of such low order that it will not cause injurious effects on human beings, said Dr. Paul A. Neal of the U. S. Public Health Service in his address to the National Museum Entomological Society here. He reported that studies conducted at the Industrial Hygiene Research Laboratory of the National Institute of Health in Bethesda, Md., showed that DDT in concentrations up to 10 per cent in inert powders for dusting clothes, as in the extermination of lice, offers no serious health consequences. The use of a 15 DDT deobase mist mixture had no toxic effect on rabbits, and it should be safe to use as a fly spray. In a clinical and laboratory study of 3 men who had had several months' continuous occupational exposure to DDT in its various forms as an insecticide, an evaluation of results failed to indicate any definite toxic effects from exposure to DDT. Although this study dealt only with the appraisal of the potential dangers of DDT when inhaled as an aerosol, dust or mist, Dr. Neal pointed out that massive doses either by mouth or by skin absorption will cause toxic reactions. Heavy contamination of foods should be avoided.

National Hospital Service Society Ordered Dissolved

Dissolution of the National Hospital Service Society, Inc., of Washington, D. C., fraternal organization providing hospitalization insurance and medical care for 5,000 District of Columbia residents, was ordered by the federal government on technical charges of violating insurance laws. District Court Justice F. Dickinson Letts consented to transfer of the five thousand policies to National Hospitalization, Inc., in Maryland. Attorneys for National Hospital Service Society state that its members do not face any loss of money or insurance benefits. Justice Letts signed a consent decree through which Cornelius H. Doherty and Louis M. Denit, attorneys, agreed to revocation of the organization's charter and dissolution of the business effective Jan. 15, 1945. U. S. Attorney Edward M. Curran and his aide Daniel B. Maher said that under terms of the charter the society was a fraternal and benefit association required to carry on its business for the sole benefit of members and beneficiaries and not for profit. The government, however, charged that the society conducted its business for profit and issued policies that did not carry death benefits and which did not require medical examinations. Such provisions were ordered for potential policyholders under the terms of the charter. The organization was founded in 1935.

Named to Joint Committee on Physical Fitness

Chairman John B. Kelly of the National Committee on Physical Fitness of the Federal Security Agency announced here that Capt. Raymond Wells, U.S.N.R., and Dr. Lon W. Morrey have been appointed to the committee as representatives of the American Dental Association. Dr. Wells is a past president of the American Dental Association, and Dr. Morrey is a member of its central office staff.

Society Proceedings**COMING MEETINGS**

- American Society of Anesthetists, New York, Dec. 14. Dr. McKinnie L. Phelps, 745 Fifth Ave., New York 22, Secretary.
- Annual Conference of State Secretaries and Editors, Chicago, Nov. 17-18. Dr. Olin West, 535 N. Dearborn St., Chicago, Secretary.
- New York State Association of Public Health Laboratories, Albany, Nov. 17. Miss Mary B. Kirkbride, New Scotland Ave., Albany 1, Secretary.
- Puerto Rico, Medical Association of, Santurce, Dec. 15-17. Dr. E. Martinez-Rivera, P. O. Box 3866, Santurce, Secretary.
- Southern Medical Association, St. Louis, Mo., Nov. 13-16. Mr. C. P. Loran, Empire Building, Birmingham 3, Ala., Secretary.
- Southern Surgical Association, Hot Springs, Va., Dec. 5-7. Dr. Alfred Bialock, Johns Hopkins Hospital, Baltimore 5, Secretary.
- Western Surgical Association, Chicago, Dec. 1-2. Dr. Arthur R. Metz, 250 East Superior St., Chicago, Secretary.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ALABAMA

Changes in Health Personnel.—Dr. John I. Mitchell, Double Springs, health officer of Winston County for three years, has resigned effective October 1 to enter private practice either in Russellville or in Pell City, it was reported.

—Dr. Frank M. Hall, Athens, has been named health officer of Alachua County, Gainesville, Fla.

ARIZONA

State Meeting to Be in Tucson.—The Arizona State Medical Association will hold its annual meeting at the Pioneer Hotel, Tucson, April 27-28, 1945. The scientific program will be presented by members of the staff of Baylor University College of Medicine, Houston, Texas.

CALIFORNIA

Symposium on Psychotherapy.—The San Francisco Psychoanalytic Society held its semiannual meeting October 28-29 at the Ambassador Hotel, Los Angeles. One session was a symposium on short psychotherapy with Condr. Uno H. Helgesson (MC) on "Experiences with Short Psychotherapy in Military Psychiatry"; Dr. Bernhard Berliner, San Francisco, "The Practice of Short Psychoanalytic Psychotherapy," and Drs. Otto Fenichel and Ernst Simmel, Los Angeles, "Theoretical Considerations of the Indications, Limitations and Technique of Short Psychotherapy." Other speakers include Drs. Emanuel Windholz, San Francisco, on "The Possibilities and Limitations of Group Psychotherapy" and Jacob S. Kasanin, San Francisco, "Vestigial Roots of Schizophrenia."

State Board Activities.—Superior Judge Emmet H. Wilson on September 12 upheld an order of the Board of Osteopathic Examiners revoking the license of Leslie R. Nunn, osteopath, on charges that he aided an unlicensed person in performing a tonsillectomy on 2 boys who died following an operation (*THE JOURNAL*, Oct. 23, 1943, p. 495). According to the *Los Angeles Examiner*, September 13, Nunn had asked for a writ of mandate compelling the board to vacate its order revoking his license as a "physician and surgeon" and charged that the board accepted evidence without his knowledge. Nunn and Harry Navarre, a chiropractor, are now in San Quentin serving terms for the deaths of 2 children who were operated on by them, it was stated.—The *San Jose Mercury Herald*, September 16, reported that probation had been granted to William G. Cardew, chiropractor and confessed abortionist. The period of the probation, which is the second in two years, is for five years. Superior Judge William F. James, in addition to making surrender of the license and abandonment of practice, equipment and drugs conditions of the probation order, also stipulated that Cardew's premises be opened for inspection at all times by county or medical authorities. Another chiropractor, Max Otto Garten, Salinas, was reported on September 17 to have been released on \$2,000 bail following his arrest on a charge of performing an illegal operation.

DELAWARE

Society News.—Dr. Percy F. Pelouze, assistant professor of urology, University of Pennsylvania School of Medicine, Philadelphia, addressed the New Castle County Medical Society of Delaware, Wilmington, October 17, on "Gonorrhea and Its Treatment." Col. Arthur P. Hitchens, M. C., discussed "Public Health and the Practicing Physician" before the society on September 19.

DISTRICT OF COLUMBIA

Dr. Ruffin Honored.—Dr. Sterling Ruffin, professor emeritus of medicine, George Washington University School of Medicine, was honored when the October issue of the *George Washington University news bulletin* was dedicated to him. The news bulletin is entitled "Confidential—from Washington" and contains a tribute by Cloyd H. Marvin, LL.D., president of the university, in which he declares that Dr. Ruffin, "as a distinguished practitioner and able teacher of medicine, has contributed greatly to the medical school and through it to the Washington community." Dr. Ruffin graduated at the medical school in 1890, serving as professor there from 1902 to 1924, when he became emeritus.

ILLINOIS

Postgraduate Conference.—The Postgraduate Conference of Northern Illinois will be held at the Faust Hotel, Rockford, November 15. Among the speakers will be:

Mr. John W. Neal, secretary, committee on medical service and public relations, Illinois State Medical Society.
Dr. William H. Cassels, Chicago, Anesthetic Emergencies.
Dr. Robert S. Berghoff, Chicago, Heart Clinic with Demonstration of Patients.
Dr. Henry G. Poncher, Chicago, Management of Rheumatic Fever.
Lieut. Col. Okla W. Sicks, M. C., Penicillin: Its Practical Applications, with Case Reviews.
Lieut. Col. Earl R. Denny, M. C., Use and Abuse of Sulfa Drugs.

New Ruling on Boric Acid.—Dr. Roland R. Cross, Springfield, state director of public health, has requested hospitals in the state to eliminate boric acid from the inventory of drugs and other preparations kept on hand for use in the maternity divisions of the hospitals. The action was taken on the ground that boric acid is of very little, if any, antiseptic value but is highly toxic when ingested by infants. The request followed the death of 2 infants in an Illinois hospital attributed to boric acid poisoning. "The infant deaths reported from various hospitals throughout the country as due to boric acid poisoning have had their origin in the accidental substitution of boric acid powder for dried milk products or of the accidental substitution of weak boric acid solution for distilled water in the preparation of infant food formulas. Carelessness, improper labeling of bottles and shifting personnel seem to be contributory factors" Dr. Cross announced.

Chicago

Personal.—Dr. Louis J. Halpern has been appointed assistant professor of pediatrics at the University of Illinois College of Medicine. —Mrs. Adaline Hayden has been appointed executive secretary of the American Association of Medical Record Librarians, effective October 23. Her headquarters will be in the office of the American Hospital Association, 18 East Division Street. —Dr. Orpheus W. Barlow, formerly director of research laboratories of Wintthrop Chemical Company, has been appointed medical and research director of Nutrition Research Laboratories. Dr. Barlow graduated at Rush Medical College in 1936.

Memorial Service for Dr. Besley.—A memorial service for the late Dr. Frederic Atwood Besley, Waukegan, will be held under the auspices of the American College of Surgeons in Memorial Hall, 50 East Erie Street, November 19, at 3 p. m. Dr. Irvin Abell, Louisville, Ky., chairman of the board of regents of the college, will preside. Taking part in the program will be Rev. Howard E. Gauster, Rector, Christ Episcopal Church, Waukegan; Dr. Irving S. Cutter, emeritus dean, Northwestern University Medical School; Major General Robert U. Patterson, M. C. (retired), Baltimore, formerly surgeon general of the Army; Dr. Gilbert J. Thomas, Los Angeles, regent, American College of Surgeons, and Dr. Donald C. Balfour, Rochester, Minn., associate, editorial staff, *Surgery, Gynecology and Obstetrics*. Dr. Besley, at the time of his death on August 16, was secretary of the American College of Surgeons, of which he was a founder-fellow in 1913.

Tumor Diagnostic Service Inaugurated.—The University of Illinois College of Medicine and the division of cancer control of the state department of public health are cooperating in a new tumor diagnostic service at the Research and Educational Hospitals, Chicago. The operation of this service under these joint auspices provides for an augmentation of the facilities offered by the tumor clinic of the medical college, which has been conducted for some time under the direct supervision of Dr. Danely P. Slaughter, assistant professor of surgery at the medical school. The activities of the state division of cancer control are under the direction of Dr. Raymond V. Brokaw, chief of the division. These facilities are available to all practicing physicians throughout the state as a consultation service in the care of their suspected cancer cases. Patients who can afford to pay will be diagnosed and returned to their referring physician with recommendations for treatment. Medically indigent patients who are approved by the social welfare department of the hospital will be treated without charge in accordance with the customary policy. Tumor clinic sessions are held on Tuesdays, Wednesdays and Fridays from 2 to 5 p. m. Ambulant patients will be admitted to the clinic on any of these days, but cases requiring hospital care will be received only by previous arrangement and to the extent of available facilities. Additional tumor diagnostic services now operated under the auspices of the division of cancer control are located at St. Anthony's Hospital, Rockford; Burnham City Hospital, Champaign, and Memorial Hospital, Springfield. At all of these services specimens of

suspected tumor tissue from medically indigent patients which may be submitted by physicians from any part of the state are accepted for microscopic examination and diagnosis without charge. Suitable containers for mailing such specimens are available upon request. Further information regarding these facilities may be obtained by addressing the Division of Cancer Control, 505 South 5th Street, Champaign, or the director of any of the services named.

INDIANA

Personal.—Dr. David A. Boyd Jr., professor of psychiatry, Indiana University School of Medicine, Indianapolis, has been made the first full time director of the neuropsychiatric ward of the Indianapolis City Hospital. —Dr. Charles A. Miller, Princeton, has been appointed health officer of Gibson County, succeeding the late Dr. Bertis C. Gwaltney, Fort Branch. —Dr. Karl R. Luthy, formerly of Paducah, Ky., has been named medical director of the U. S. Rubber Company plant in Mishawaka.

LOUISIANA

Dr. Bayley Goes to Oklahoma.—Dr. Robert H. Bayley, associate professor of medicine, Louisiana State University School of Medicine, New Orleans, resigned September 1 to become professor of medicine at the University of Oklahoma School of Medicine, Oklahoma City.

MARYLAND

Evander F. Kelly Dies.—Evander F. Kelly, Phar.D., a member of the Maryland State Department of health since 1920 and secretary of the American Pharmaceutical Association, died at his home in Texas, Baltimore County, October 27. Dr. Kelly had been dean of pharmacy at the University of Maryland from 1918 to 1926, when he became advisory dean. In 1933 he won the Remington Medal of the American Pharmaceutical Association.

Emmett Holt Goes to New York Medical College.—Dr. L. Emmett Holt Jr., since 1930 associate professor of pediatrics at Johns Hopkins University School of Medicine, Baltimore, has been appointed professor of pediatrics at the New York University College of Medicine and director of the pediatric service at Bellevue Hospital. Dr. Holt graduated at Johns Hopkins in 1920 and has been a member of the staff there since 1922. He was president of the Society for Pediatric Research in 1939.

MICHIGAN

Bequest for Cancer.—About one million dollars of the estate of Mrs. James T. Pardee, Midland, is to be used for the control of cancer under her will, the New York Times reported October 12.

Personal.—Dr. John H. Law, formerly assistant director of Grace Hospital, Detroit, has been named director, succeeding the late Dr. Edmund F. Collins. —Dr. Milton H. Erickson, assistant professor of psychiatry at Wayne University College of Medicine, Detroit, has recently been promoted to associate professor of psychiatry. —Dr. Henry J. Pyle, Muskegon, has resigned as school physician of Muskegon, a position he has held for the past twenty-four years.

State Division of National Physicians Committee.—The Michigan Division of the National Physicians Committee for the Extension of Medical Services was organized at the Book-Cadillac Hotel, Detroit, October 11. Dr. Clarence E. Umphrey, Detroit, who has served for a number of years as chairman of the Metropolitan Detroit Group, was unanimously elected chairman of the state committee, which will now absorb the former Metropolitan organization. Other officers chosen include Drs. William M. LeFevre, Muskegon, vice chairman; Eldwin R. Witwer, Detroit, secretary, and Wyman D. Barrett, Detroit, treasurer. These officers will consider the appointment of an executive secretary.

Scholastic Prizes.—The Distinguished Service Award of Wayne University College of Medicine, Detroit, was presented during the recent commencement to Dr. Kenneth E. McIntyre as the "student outstanding in scholastic and extracurricular activities." Dr. Donald E. Preshaw received the Alumni Award, presented to the student who has maintained the highest scholastic standing during his four years in college. The Theodore A. McGraw Memorial Award, given to the outstanding student of the junior year, went to Peter J. Talso. This prize was given to Dr. Preshaw during his junior year. Arthur D. Harris and Dr. Addison E. Prince received the H. Peyton Johnson scholarships, presented annually to Negro medical students of high ability and character. The Angus McLean Memorial Award, for the graduate student who has done the best research work during the year, went to Dr. Robert O. Bauer.

NEW HAMPSHIRE

Health Program at Colby College—Seventeen physicians conducted an annual health clinic at the Colby Junior College, for women, New London, October 21, examining the 190 entering students and reviewing the cases of returning students whose previous health records have not been perfect. Serving as the basis for the clinical work are the records presented by the student's family physician and results of the college's preliminary examination covering chest x-ray, hemoglobin test, heart rate, blood pressure, Wassermann test, urinalysis, blood analysis and audiometric reading. Following her examination each student meets with one of the conference physicians to clear up any questions and to determine her health program for the year. Where necessary appointments are made at neighboring clinics and hospitals for psychiatric treatment and dental work. In preparation for the clinic three medical technicians graduates of Colby, have worked at the New London Hospital for two days to analyze specimens and to complete Wassermann tests. Undergraduates in the medical technician and medical secretarial courses receive practical experience at the clinic in making records and otherwise assisting the doctors. In addition to its purpose in preventing disease and discovering physical weaknesses the clinic is considered an effective educational measure in that it familiarizes students with complete, efficient and modern medical methods and, through the personal doctor-student conference, gives them an opportunity to gain the maximum knowledge from the experience. The estimated expense to the college for the one day clinic is approximately \$2,000. The college stresses the importance of student, faculty and staff health throughout the year. Faculty, housekeepers and groundsmen are required to pass a complete physical examination at least every three years, while food handlers must undergo an annual examination that is thorough in every respect and designed to discover carriers of infection. A daily clinic is held every morning for students to check on slight illnesses and to segregate immediately those who need hospitalization in the college infirmary.

NEW YORK

Another Medical Plan—At a meeting October 17 the Medical Society of the County of Monroe voted to launch the Genesee Valley Medical Care Inc., a nonprofit medical insurance plan for residents of the Rochester area. The name was selected to make the plan broad enough to attract medical persons in the area but outside Monroe County. A board of ten directors and two others to be named by the president of the society, Dr. Benedict J. Duffy, Rochester, will work with six lay members of the board of directors in planning details to submit to interested agencies.

Meeting of Public Health Laboratories—The New York State Association of Public Health Laboratories will meet at the state laboratory, Albany, November 17. Among the speakers will be

- Dr. William Kaufmann, Albany, Laboratory Aids in the Diagnosis of Amebic Colitis in Temperate Climates
- Dr. Nathan Mitchell, Albany, Latent Primary Carcinoma of the Thyroid Gland
- Dr. Frank W. Foote Jr., Albany, Mucoepidermoid Tumors of Salivary Glands
- Dr. Max M. Strumler, Bryn Mawr, Pa., Fractionation of Blood with Specific Reference to Modified Globin

On November 16 the association will sponsor its fifth conference on tropical diseases in cooperation with the division of laboratories and research of the state department of health. Participating will be Dr. George M. Lewis, New York, who will discuss "Clinical and Immunological Aspects of Fungus Infection" and Rhoda W. Benham, Ph.D., New York, "Laboratory Procedures in the Diagnosis of Fungus Diseases."

Resources to Be Pooled in Poliomyelitis Care—A plan is under consideration in New York State whereby personnel and resources can be pooled to meet the need for postacute and convalescent care of victims of this year's outbreak of infantile paralysis. At a meeting of hospital administrators called by the state department of health, September 26, Dr. Edward S. Rogers, assistant commissioner for medical administration, stated that the estimate of cases in upstate New York will reach 4,000 by the end of the present outbreak, now past its peak, equaling the figure for the epidemic of 1916. According to *Health News*, publication of the state department of health, this does not hold true for New York City, the expected total for which is 1,800 cases, only about one fifth of the number experienced in 1916. The group attending the meeting expressed serious concern over the problem in future months of providing the facilities required to meet upstate demands and a resolution was approved providing for the appointment of a state commissioner of health of an advisory coordinating committee to consist of three representatives of each of

the following groups: the Hospital Association of New York State, the New York State Association of Institutions for the Physically Handicapped and the New York State Department of Health. A function of the committee will be, among other things, to evaluate the needs of the postepidemic poliomyelitis period and to make recommendations to the commissioner of health concerning the allocation of personnel and patients to institutions qualified to care for such patients.

New York City

The Harvey Lecture—Selman A. Waksman, Ph.D., microbiologist, Agricultural Experiment Station, State of New Jersey, New Brunswick, will deliver the second Harvey Society Lecture of the current series at the New York Academy of Medicine November 16. His subject will be "Production and Nature of Antibiotic Substances."

Industrial Hygiene Courses—A series of one week courses in the medical, surgical and dental aspects of industrial hygiene opened at the DeLamar Institute of Public Health, Columbia University, October 30, and will continue to December 16. The program is designed to aid in the institutes expanding plan for teaching, practice and research in various aspects of public health. Studies in diagnosis and control of dermatoses began October 30. Other courses will be on general health in industry, to start November 13; the use of plasticizers and solvents in industry and their toxicologic aspects, November 20; metals and their industrial uses and dangers, November 27; and the administrative aspects of industrial hygiene, December 4. Dental problems and practices in the field of industrial hygiene will be the subject of the final course in the series, to begin on December 11.

Rehabilitation Project—The Hospital for Joint Diseases and the New York City Vocational Rehabilitation Bureau have worked out a joint program directed toward the early vocational rehabilitation of patients known to that hospital. The plan calls for an analysis of the social and vocational needs of the patients based on the medical survey, diagnosis and prognosis before patients are discharged from the hospital. Consideration will be given as to whether a patient can return to his former job, whether he requires assistance in returning to his previous job or work environment, whether he requires counseling and guidance in his job adjustment or whether he requires training or retraining toward a job objective. Where patients are discharged from the hospital to continue under medical care, consideration of medical, social and vocational needs of the patient will continue after his discharge from the hospital until the plan for the patient is fulfilled. This early consideration will aim to balance the patient's physical and psychologic capacity to the demands of the training and retraining program and the job objective as outlined. The project is under the direct guidance of the medical board which has assigned several of its members to the rehabilitation committee. In this project, in which the doctors will take leadership, all departments of the hospital will be involved including medical, nursing, social service, occupational therapy and physical therapy. The New York City Vocational Rehabilitation Bureau has assigned a member of its staff to the joint rehabilitation project who is serving at the hospital.

Postwar Plans Feature Dinner for Physicians—A dinner was held at the Hotel Roosevelt, October 26, celebrating the seventieth birthday of Drs. Samuel A. Brown, formerly dean of the New York University College of Medicine and George B. Wallace, professor of pharmacology at the college. The occasion also observed the many years of service of both physicians, Dr. Brown having been associated with the college since 1896, two years after his graduation there, and Dr. Wallace who has been associated with the teaching faculty since 1901. Dr. Brown served as dean from 1915 to 1932. He is currently chairman of its council committee on medicine and dentistry. Harry Woodburn Chase, LL.D., chancellor of the university, as a guest speaker, announced extensive postwar plans for the development of a medical-dental center in the Bellevue area by the New York University College of Medicine in cooperation with the city of New York and Bellevue Hospital. The plans would include a university hospital and diagnostic clinic which would offer all methods of modern diagnosis together with inpatient facilities to families of the middle-low income group, an institute of medical sciences where the clinical departments of medicine can offer opportunities to younger men for study and research in the important fields and a general unit which would comprise the medical library, hall of residence and a large auditorium for postgraduate teaching to seat 500. In announcing the proposed plans, Dr. Chase paid tribute to Dr. Brown and Dr. Wallace for their efforts in the development of the New York University College of Medicine.

OREGON

Frank Menne Retires as Professor of Pathology.—Dr. Frank R. Menne, since 1916 associated with the University of Oregon Medical School, Portland, has resigned as professor and head of the department of pathology. He has been succeeded by Dr. Warren C. Hunter, a member of the staff of the school since 1925. Dr. Menne graduated at Rush Medical College in 1915, going to Oregon the following year to become assistant professor of pathology. He was named professor in 1920 and head of the department in 1929. Dr. Hunter graduated at Oregon in 1924, joining the faculty the following year as assistant professor of pathology. He was named professor in 1941.

RHODE ISLAND

Fraudulent License Revoked.—On August 9 the state board of medical examiners revoked the license to practice medicine issued to Charles Jacobson, 984 Broad Street, Providence. Appeal by Jacobson subsequent to this action serves as a stay of the revocation until the case is disposed of by the supreme court. The state board of medical examiners contends that Jacobson obtained his license to practice through fraud and deceit. It is reported that there is no evidence to prove that Jacobson had taken and passed his state examination in 1934 as he claimed, and members of the board testified that they did not recall that he took the examination. A physician testifying at the trial, who took the examination in question, testified that he did not see Jacobson present at the time and that Jacobson later came to him and asked him to state that he had seen the latter take the examination. Information concerning Jacobson shows that he graduated at the Middlesex College of Medicine and Surgery, Waltham, Mass., in 1932 and served an internship at the Miriam Hospital, Providence, from July 1932 to July 1933. He is reported to have taken the Massachusetts State Board examinations in 1934 and 1935, failing to pass in either of them.

SOUTH CAROLINA

Changes in Health Officers.—Dr. Robert D. Hicks, director of the York and Chester district health department, has also been placed in charge of the unit at Cherokee County with headquarters in Chester. —Dr. James N. Holtzclaw, director of the Greenville County Health Department, has been given jurisdiction over the unit in Laurens County.

Young Physician Wins Ravenel Cup.—Lieut. (jg) Harry Boatwright (MC), who graduated at the Medical College of the State of South Carolina, Charleston, September 16 and who has received a commission in the U. S. Naval Reserve, was during his graduation exercises presented with the Ravenel Cup for his thesis in the field of public health. The cup is awarded annually by Dr. Mazyck P. Ravenel, formerly of Charleston and now emeritus professor of medical bacteriology and preventive medicine in the University of Missouri School of Medicine, Columbia.

TEXAS

Proposed Expansion Program at State Medical School.—Chauncey D. Leake, Ph.D., dean and executive vice president, University of Texas School of Medicine, Galveston, recently recommended a long range expansion program estimated to cost about four million dollars to meet the physical needs of the school of medicine. The recommendations were contained in a report to the medical committee of the board of regents of the university and include an addition of the main laboratory building to cost \$1,000,000, a library auditorium and general administration building \$300,000, and a building for a school of public health which, according to the state medical journal, probably could be housed in the main building of the medical college if other departments are transferred. The transfer of the Galveston State Psychopathic Hospital to the medical college to provide exceptional facilities for psychiatry was also recommended. Immediate needs proposed by Dr. Leake include: estimated repair costs, \$10,000; pediatric clinical laboratories, \$2,500, which will come from the Buchanan Foundation; pediatric experimental facilities, \$15,000 from the Buchanan fund; housing for women medical students, \$40,000, and locker rooms for hospital help, \$12,000. Dr. Leake also recommends that legislative appropriations be increased to provide appropriate salaries to insure additional teachers necessary to reach a reasonable approach of the optimum teacher-student ratio for American medical schools of one instructor to ten students per course, and that a salary scale be provided that will assure competent teachers and research workers. The salary range in the preclinical departments of the better medical schools of the United States, it was stated, is as follows: for

full time faculty members—professor, \$12,000 to \$16,000; associate professor, \$6,000 to \$10,000; assistant professor, \$4,500 to \$8,000; instructor, \$3,000 to \$6,000; assistant, \$2,000 to \$3,600.

WEST VIRGINIA

Questionnaires to Determine Psychiatric Program.—Results of questionnaires will be presented to the council of the West Virginia State Medical Association at its meeting this month to determine what part, if any, the association will take to provide a general program on psychiatric education for practicing physicians in the state. Of the 350 physicians whose questionnaires have been reviewed, 90 per cent would like additional knowledge on psychiatry and at least 80 per cent would like to know more about emotional illness. Less than 15 per cent of the physicians replying to the questionnaire sent out by the state society in August stated that they have had any training or developed any working concept in psychiatry. Almost all of the replies indicate a general lack of psychiatric assistance in the state. More than 90 per cent of the physicians are interested in seminars on psychiatry to be held evenings at meetings of component medical societies, and 50 per cent of the group expressed their willingness to pay a nominal attendance fee. Seventy per cent signified their willingness to have a symposium on psychiatry presented in the *West Virginia Medical Journal*. The returned questionnaires indicated that doctors would be willing to have psychiatry presented in simple terminology and related to general medicine, with stress being placed on the handling of psychoneuroses, subclinical personality problems and psychosomatic disturbances.

Medical Societies Merge.—On October 20 the Lewis County Medical Society was merged with the Central West Virginia Medical Society, carrying out a unanimous vote of both groups. The consolidation of the two societies will mean an active roll of more than fifty doctors. The Lewis County Medical Society includes physicians in Gilmer County, and members of the enlarged Central West Virginia Medical Society residing in six adjoining counties can conveniently meet at the county seat in any of these communities. The Lewis-Upshur Medical Society was organized in 1899 principally through the efforts of Dr. Thomas M. Hood, Clarksburg, who recently died in that city at the age of 91 years. That same year the state medical association held its annual convention at Weston and the late Dr. Charles S. Hoffman, Keyser, was elected president. In 1915 the doctors of Upshur County withdrew from the Lewis County Medical Society and became members of the Central West Virginia Medical Society, then composed of doctors residing in Nicholas, Braxton and Webster counties. Three members of the Lewis County Medical Society who were charter members at the time of the organization of the Lewis-Upshur Society are still in practice at Western and are members of the Lewis County Medical Society. These members, Drs. George Snyder, Wessie P. King and Edward T. W. Hall, are now honorary life members of the local society and the state medical association.

GENERAL

Pediatric Society Opposes Children's Bureau Transfer to Public Health Service.—At a meeting of the American Pediatric Society in Atlantic City, N. J., September 25-27, a resolution was adopted affirming the society's wish to continue the hitherto good relations between it and the Children's Bureau. Other resolutions affirmed that no change in the method of payment in the EMIC program is warranted or desirable and that the transfer of the health services of the Children's Bureau to the U. S. Public Health Service, contained in the Miller bill now before Congress, is undesirable. The resolution points out that this transfer would separate medical care from the other essential aspects of child care and emphasizes that the Miller bill does not make any provision for the development of a National Department of Health. Dr. C. Anderson Aldrich, Rochester, Minn., was chosen president of the American Pediatric Society during this meeting. Dr. Charles Hendee Smith, New York, vice president and Dr. Hugh McCulloch, St. Louis, secretary-treasurer. Dr. Heyworth N. Sanford, Chicago, is the recorder-editor.

The Poliomyelitis Situation.—The 1944 epidemic of infantile paralysis has officially become the second worst in the recorded history of the disease in the United States, the National Foundation for Infantile Paralysis announced October 29. In the first forty-one weeks of 1944, or up until October 14, there were 16,133 cases of poliomyelitis, according

to the latest report from the U. S. Public Health Service. This is 353 cases more than were reported in the country for 1931, which previously had been the second worst year for the disease. The all time record was in 1916, when there were 27,621 cases. Although the peak of the outbreak had been passed a month before this report, the epidemic itself has not yet ended, it was stated. There were 710 new cases reported for the week of October 7-14, or nearly half the weekly total at the peak of the epidemic, the week ended September 2, when 1,683 cases were reported. The seven states most severely menaced were New York, North Carolina, Pennsylvania, New Jersey, Virginia, Ohio and Kentucky, but emergency aid in the form of money, professional personnel and supplies has been sent this year by the National Foundation to twenty-one states and the District of Columbia.

Earl Bonnett Named Medical Director of Metropolitan Life.—Dr. Earl C. Bonnett, associate medical director of the Metropolitan Life Insurance Company, New York, has been appointed medical director of the company, to succeed the late Dr. Charles L. Christiennin, who died October 18. In his new capacity Dr. Bonnett will supervise a staff of about 8,000 physicians who serve as medical examiners for the Metropolitan in the United States and Canada. He will be responsible for the formulation of rules for the medical examination of applicants for insurance and advise in the establishment of rules for the selection of risks. His duties will also involve the management of home office health activities, which include the medical care and periodic physical and dental examinations of some 14,000 employees. Dr. Bonnett graduated at Cornell University Medical College in 1923 and joined the staff of the Metropolitan as a medical examiner in the home office in 1926. He was advanced to official rank as assistant medical director in 1928 and promoted to associate medical director in 1944.

Music in Therapy.—The National Music Council recently conducted a survey to ascertain to what extent music is currently used in leading nervous and mental disease hospitals throughout the country. Two hundred and nine hospitals with various bed capacities answered a questionnaire. Only 192 of the 209 used music. The rest were refrained from adopting this form of therapy by war restrictions and economics, shortage of personnel and lack of facilities. There are performances in 160 hospitals by visiting artists, gifted patients, church choirs, bands and glee clubs. Recorded music is played by 152 institutions. Only 23 hospitals reported that they used music for therapeutic reasons, and 134 used it for both recreation and therapy. According to a report in the *New York Times*, most directors of hospitals find that "recreation is therapy." Active participation in the making of music is generally considered more effective than mere listening. Group performance develops a spirit of cooperation and fellowship and helps patients to overcome their inhibitions. The psychiatric staff of one hospital finds that the blare and dissonance of jazz "is a disturbing influence to all types of patients." Band music, spirituals, American folk songs are soothing. But music is not a specific for mental disorders, it was stated; there is even the danger that the wrong music may be used by patients to express and reinforce delusional ideas.

National Research Council Named for Pharmaceutical Award.—The American Pharmaceutical Manufacturers' Association announces that the National Research Council has been chosen for its sixth annual award "in recognition of its fundamental contributions to public health in the field of medical sciences and of its essential services to the country in World Wars I and II." The award will be presented during the final day's session of the two day meeting of the American Pharmaceutical Manufacturers' Association at the Waldorf-Astoria, New York, December 11-12. Among the speakers in a program devoted to some fundamental trends in chemotherapy will be:

Dr. John S. Lundy, Rochester, Minn., Progress in Conquest of Pain by New Anesthetics.
Dr. Chester S. Keefer, Boston, Progress in Conquest of Bacteria by New Medicinal Agents.
William C. Rose, Ph.D., Urbana, Ill., Progress in Conquest of Malnutrition by Amino Acids.
Edwin J. Cohn, Ph.D., Cambridge, Mass., Progress in Conquest of Disease by Blood Proteins.
Wendell M. Stanley, Sc.D., Princeton, N. J., Progress in Conquest of Disease by Virus Proteins.

Dr. Alan Gregg, New York, director of medical sciences, Rockefeller Foundation, will give the presentation address, on "Essential Need of Fundamental Research in Medical Sciences for Social Progress," and Dr. Ross G. Harrison, New Haven, chairman of the National Research Council, the acceptance address, entitled "National Research Council and Its Action in Field of Medical Sciences."

LATIN AMERICA

Health Activities in Latin America.—*Personal.*—Lieut. Col. Leon H. Collins Jr., M. C., who practiced in Philadelphia before entering military service in 1942, has been appointed section chief at Gorgas Hospital, Ancon, Canal Zone.

Report of Health and Sanitation Division.—A summary of activities of the health and sanitation division, Office of the Coordinator of Inter-American Affairs, has recently been published. Between February 1942 and July 1943 agreements for cooperative health work were signed with fifteen of the other American republics, according to the Newsletter of the division. Mexico was added in July 1943, the Dominican Republic in August 1943 and Uruguay in November 1943. Twelve republics which arranged to extend the program for periods of two and one-half to five years include Brazil, Colombia, Costa Rica, the Dominican Republic, El Salvador, Honduras, Mexico, Nicaragua, Peru, Paraguay and Venezuela. Renegotiations for Bolivia and Guatemala are pending. The report states that more than six hundred activities are under way or completed in the southern countries including 300 jobs for environmental improvement by permanent mosquito control measures, water supplies, sewerage systems and general sanitation. Construction work includes provision or improvement of facilities for a total of about one hundred and forty health centers, hospitals, infirmaries, dispensaries and other buildings. Over two hundred activities are devoted to provision of medical care and preventive services through operation of hospitals, health centers, clinics and laboratories, surveys and research in disease control, local training courses and widespread health education for the lay public. Although the division was established in February 1942, the report indicates the expansion of its activities during the period July 1, 1943 through June 30, 1944, in which projects reported completed total one hundred and forty-three and include complete construction, additions to or remodeling of sixteen hospitals, seventeen health centers, twelve dispensaries and fifteen other buildings. Health centers were completed at Encarnacion and Concepcion and in the Barrio Obrero District of Asuncion. In the latter a combination 50 bed hospital and health center was constructed, with x-ray and laboratory sections to serve both units. Since September 1943, operation and maintenance of the hospital section has been carried on by the ministry of health, with supervision of all nursing personnel by a United States nurse serving with the field party. Operation of the health center is a cooperative project, with a Paraguayan doctor serving as health officer. Cooperative direction of medical facilities and specific disease control services was terminated by the completion of some thirty projects, many of which were turned over to the national departments of health for continuing operation. These included plague control in Ecuador and treatment services in many areas of Colombia. In other instances the closed projects consisted of prevalence surveys or were of an emergency nature, such as those in El Salvador. Here medical services were provided for the care and improvement of the health of employees on the Pan American Highway from March 10 through September 30, 1943. A medical supervisor had headquarters at Santa Rosa. Malaria surveys were made by means of routine blood smears and cases treated with quinine and atabrine. Inspections were also made periodically to diagnose and treat venereal disease. The project was in cooperation with the department of public works of the republic of El Salvador and the U. S. Army engineers in charge of the Pan American Highway. Under the professional training program arrangements were made for 212 persons from the other Americas for study or travel grants in the United States. These consisted for the most part of physicians or engineers who were enrolled in schools of public health for courses leading to certificates or degrees in this field.

CORRECTIONS

Globin Insulin.—The second article of the July issue of the *Annals of the District of Columbia* listed in THE JOURNAL, October 7, should read "Comparative Study of Action of Globin Insulin with Other Forms of Insulin. M. Protas." The word Globulin is a misprint in THE JOURNAL.

Modified Miller-Abbott Tube.—At the request of Dr. Franklin I. Harris, who wrote "A New Rapid Method of Intubation with the Miller-Abbott Tube" (THE JOURNAL, July 15) credit should be given to Dr. Ivar Sivertsen for independent use of metallic mercury in the balloon of the Miller-Abbott tube. This modification of the Miller-Abbott tube was mentioned in a paragraph in the book by Wangenstein entitled "Intestinal Obstruction," second edition, page 164.

Foreign Letters

LONDON

(From Our Regular Correspondent)

Oct. 11, 1944.

Workmen's Compensation to Be Taken Over by the Government

The expansion of medical socialism, in the form of compulsory social insurance, has been described in a previous letter. In a further paper the government has outlined proposals for a new industrial injury insurance scheme to replace the present system of workmen's compensation. The legal liability of the employer to compensate an employee for loss of earning capacity due to accident or industrial disease arising out of his employment is swept away, and provision for disablement or loss of life from industrial injury or specified industrial diseases becomes a social service. This fundamental change is based on the recommendations of the Beveridge scheme, but the benefits are substantially more generous. Instead of being related to loss of earning capacity, as under the existing compensation law, the benefits will be paid on flat rates, with supplements for family responsibilities. A financial responsibility which rests on the employer will now be shared by him, the employee and the state. Contributions will be 12 cents a week for adult men and 8 cents for adult women, and half these rates for boys and girls under 18. Employers will pay the same amounts. The scheme will apply to the 18,000,000 employed persons in the social insurance scheme.

A workman incapacitated by an industrial injury will receive \$7 a week up to thirteen weeks, with \$1.75 added for a wife and \$1 for the first child. Allowances for other children will also be payable under the family allowances scheme. If the disablement is likely to be permanent or prolonged, the allowance will be replaced by an industrial pension based on a medical assessment of the degree of disability. The pension rate for total disability will be \$8 a week, with allowances of \$2 a week for a wife and \$1.50 for the first child. Benefits are also payable to a widow or to other dependents on the death of an insured person. Before the war, workmen's compensation cost employers \$40,000,000 a year, which was increased to \$68,000,000 by wartime legislation. Under the new scheme benefits are estimated to cost \$80,000,000 annually, with a further \$12,000,000 required for administration. One sixth of the cost will be borne by the state, and the rest in equal shares by employers and employees. Thus the cost to either of the latter will be something less than \$40,000,000 a year. A great merit claimed for the new scheme is that it will remove workmen's compensation from the atmosphere of conflict with which it has been surrounded and avoid the ultimate recourse to litigation between employer and workman.

Sir Humphry Davy Rolleston

The death at the age of 82 of Sir Humphry Davy Rolleston, September 24, removes a prominent figure in British medicine. He came of a family distinguished in science, his father being George Rolleston, M.D., F.R.S., Linacre professor of physiology at Oxford, and his mother a niece of the physicist Sir Humphry Davy. He was educated at Cambridge, where he had a distinguished career, and at St. Bartholomew's Hospital. After serving as house physician and demonstrator of anatomy he wrote "A Manual of Practical Morbid Anatomy." He was appointed assistant physician to St. George's Hospital, where he taught pathology. He became associated with Sir Clifford Allbutt, regius professor of medicine at Cambridge, and assisted him in the preparation of his "System of Medicine" in eight volumes, which appeared from 1896 to 1899 and for many years was a leading textbook of medicine. In the revised edition,

which appeared from 1906 to 1911, his name appeared as co-author. He wrote several of the articles, notably those on alcoholism, diseases of the esophagus, small intestine, adrenal glands, spleen and lymphatics. In 1925, on the death of Allbutt, he succeeded to the professorship. He was examiner in medicine in most of the universities and in 1922 was president of the Royal College of Physicians.

What distinguished him most was prodigious learning and utmost accuracy as a writer and editor. In his Harveyan Oration on Cardiovascular Diseases he quoted some three hundred authors. The first important work to appear under his name was "Diseases of the Liver, Gallbladder and Bile Ducts," published in Philadelphia in 1905. A third edition, in which Prof. J. W. McNee cooperated, appeared in 1929. Among shorter works from his pen were "The Medical Aspects of Old Age," an essay on "Writing Theses for the M.B. and M.D.," which was a useful medicoliterary help, and the Osler memorial oration. He was the author of innumerable addresses and articles. In 1936 he began the editorship in twelve volumes of the British Encyclopedia of Medical Practice, writing many of the sections himself. From 1928 almost until the time of his death he was editor of the *Practitioner*. He took part in much administrative work, sitting on numerous government committees—the Medical Consultative Board for the Navy, the Medical Administrative Committee of the Royal Air Force, the Royal Commission on National Health Insurance, the Royal Commission on Lunacy and Mental Disorder and the Colonial Committee on Medical Services. In his full life he was much respected for his integrity, perfect courtesy and devotion to truth.

The Medical Staff at Arnhem

Of the 6,500 air borne troops landed at Arnhem, only 2,000 returned unscathed after nine days' almost sleepless fighting. Some 1,200 wounded had to be left behind, but a wounded officer who afterward escaped said that the Germans were treating them with consideration. The divisional medical staff of all ranks chose to stand by their patients and went with them into captivity. A staff officer stated that the action of this fine division contributed much to the success of the operation, which should be looked on not as a brilliant failure but as an expensive success.

Marriages

DOROTHY E. DONLEY, Columbus, Ohio, to Mr. Thomas P. Dowd of Somerset, Md., in Washington, D. C., September 4.

GEORGE HENRY BUNCH JR., Columbia, S. C., to Mrs. Nancy Riddleberger Hutchinson in Washington, D. C., October 1.

JOSEPH F. CORSAO, Cleveland Heights, Ohio, to Miss Dorothy Elizabeth Yopko of Munhall, Pa., September 23.

RICHARD HENRY STANTON, Newton, Mass., to Miss Elizabeth Cecilia Eichorn of West Medford, September 4.

JAMES NATHAN SLUDGE JR., Greensboro, Ala., to Miss Evelyn Camille Wohlers of Yakima, Wash., September 2.

MARVIN S. ALTER, Salt Lake City, to Miss Ellen Scott of San Gabriel, Calif., in Los Angeles recently.

WALTER RANDOLPH CHITWOOD, Wytheville, Va., to Miss Ruth Anne Reed of Willis, September 18.

THOMAS D. DUANE, Peoria, Ill., to Dr. JULIA A. McELHINEY of Iowa City, Iowa, March 22.

THOMAS B. DANIEL, Oxford, N. C., to Miss Bette Margolis of Worcester, Mass., September 13.

HUGH HYDEN GREGORY, Dalton, Ga., to Miss Myrtle Louvenia Durham of Atlanta, September 21.

JAMES J. BARROCK, Milwaukee, to Miss Marie Theresa Rany of Mankato, Minn., September 4.

LEONARD M. VAN STONE to Mrs. Emelie Culbertson Kistler, both of Denver, August 8.

SAUL ROY KOREY to Miss Doris Evelyn Broder, both of New York, October 15.

Deaths

Milbank Johnson, Pasadena, Calif.; Northwestern University Medical School, Chicago, 1893; member of the California Medical Association and the Southern California Medical Association; chairman of the special medical research committee at the University of Southern California, Los Angeles; professor of physiology and clinical medicine from 1897 to 1901; for twelve years, from 1901 to 1913, chief surgeon for the Southern California Edison Company; president of the Municipal Charities Commission, Los Angeles, from 1913 to 1917; vice president and director of the Pacific Mutual Life Insurance Company from 1917 to 1936; director of the American Insurance Federation since 1917; president of the Western States Taxpayers Conference and the California Taxation Improvement Association, 1925-1926; since 1926 chairman of the board of directors of the California Taxpayers Association; director and member of the executive committee of the National Tax Association; member of the board of directors of the Pasadena Hospital Association; served as a member of the board of health of Los Angeles from 1900 to 1904 and as a member of the board of freeholders which revised the Los Angeles city charter in 1916; member of the executive committee of the California Military Welfare Commission during World War I; member and past president of the California Conference of Social Agencies; vice chairman of the California Educational Aid Foundation; president of the Southwest Museum from 1920 to 1926; received the LL.D. from the University of Southern California in 1917 and Northwestern University in 1920; since 1942 member of the city defense council and the Red Cross Emergency; died in the Huntington Memorial Hospital October 3, aged 72.

Sidney Morrill McCurdy ♂ St. Johnsbury East, Vt.; Western Reserve University Medical Department, Cleveland, 1904; resigned in 1941 as chief medical director of the Ohio State Industrial Commission, a position he had held since 1936; during World War I served as a captain in the medical corps, 18th Infantry, first division, and had been awarded the Croix de Guerre, the Bronze Star and the Presidential citation for bravery; recommended for the Distinguished Service Medal; member of a committee on industrial sanitation formed in 1915 by the Section on Preventive Medicine and Public Health of the American Medical Association; lecturer on industrial medicine at the Ohio State University College of Medicine, Columbus for many years; past president of the Mahoning County (Ohio) Medical Society; formerly chief surgeon of the Youngstown Sheet and Tube Company in Youngstown, Ohio, and medical director of the Plumbrook Ordnance Works in Huron, Ohio; served as a member of the staffs of the Youngstown Hospital, Youngstown, Ohio, and the Brightbrook Hospital, St. Johnsbury; died September 26, aged 63.

Ralph Garfield Mills ♂ Decatur, Ill.; Northwestern University Medical School, Chicago, 1907; an Associate Fellow of the American Medical Association; aided in building the Kennedy Hospital, Kangkai, Korea, of which he was head from 1908 to 1912; professor of pathology and bacteriology and in charge of the clinical laboratories and research department, Severance Union Medical College, Seoul, Korea, from 1913 to 1918; served as head of the department of pathology in Peking Union Medical College and as instructor in pathology at Johns Hopkins University, Baltimore; formerly professor and head of the department of pathology at the University of Colorado School of Medicine, Denver; entered the Mayo Clinic, Rochester, Minn., as an associate in pathologic anatomy and later became professor of pathology at the University of Minnesota, Graduate School; formerly on the staff of St. Agnes Hospital, Fond du Lac, Wis.; member of the American Association of Pathologists and Bacteriologists and the Wisconsin Academy of Science; died in St. Mary's Hospital October 17, aged 63.

Laird Sumner Van Dyck ♂ New York; Rush Medical College, Chicago, 1924; associate in dermatology and syphilology at the New York Post-Graduate Medical School, Columbia University; specialist certified by the American Board of Dermatology and Syphilology; member of the American Academy of Dermatology and Syphilology; diplomate of the National Board of Medical Examiners; served on the staffs of the Well-Born Hospital for Chronic Diseases and the New York Skin and Cancer Hospital; chief of clinic, attending dermatologist and syphilologist to the dispensary, and assistant attending dermatologist and syphilologist, New York Post-Graduate Hospital, where he died August 9, aged 51, of generalized lymphosarcoma-tosis.

Edward Charles Podvin ♂ New York; Albany Medical College, Albany, N. Y., 1898; member of the House of Delegates of the American Medical Association in 1941, 1942 and 1943; assistant secretary of the Medical Society of the State of New York; executive secretary and past president of the Bronx County Medical Society; past president of the Catholic Physicians' Guild; chairman of the Bronx Tuberculosis and Health Committee; on the consulting staffs of the Fordham and St. Francis hospitals; in 1935 appointed by Governor Lehman a member of the state industrial council; editor of the *Bulletin of the Bronx County Medical Society*; died September 27, aged 68, of arteriosclerosis.

James Moorhead Murdoch ♂ Pittsburgh; Western Pennsylvania Medical College, Pittsburgh, 1892; member of the American Psychiatric Association, the Central Neuropsychiatric Association and the Association for Research in Nervous and Mental Disease; president of the American Association on Mental Deficiency in 1903 and secretary from 1917 to 1921; formerly instructor in histology and pathology at his alma mater; for many years physician and superintendent of the State Institution for the Feeble-minded of Western Pennsylvania, Polk; superintendent of the Minnesota School for Feeble-minded at Faribault from 1927 to 1937, when he resigned; died October 9, aged 75.

Saul Berman ♂ Boston; Harvard Medical School, Boston, 1920; specialist certified by the American Board of Obstetrics and Gynecology, Inc.; formerly assistant in obstetrics at his alma mater; served an internship at the Boston City Hospital; formerly a resident physician at the Boston Lying-in Hospital; on the staffs of the Newton Hospital, Newton, Massachusetts Women's Hospital, New England Hospital for Women and Children and the Boston Lying-in Hospital; founder of the fertility clinic and laboratory at the Beth Israel Hospital; died in the New England Deaconess Hospital September 18, aged 48, of carcinoma of the testis and uremia.

Harlan Herbert Staats ♂ Charleston, W. Va.; Barnes Medical College, St. Louis, 1899; an Affiliate Fellow of the American Medical Association; honorary member of the Kanawha County Medical Society and the West Virginia State Medical Association; during World War I served in the medical corps of the U. S. Army as a plastic surgeon with evacuation hospital number 41 and had been honorably discharged with the rank of captain; founder and president of the Staats Hospital; formerly surgeon in charge of the Roane County Hospital, Spencer; died in a Huntington hospital September 30, aged 68, of myocardial failure.

Wilbur Stuart Wood, Decatur, Ill.; University of Illinois College of Medicine, Chicago, 1925; member of the American Academy of Orthopaedic Surgeons and the Illinois State Medical Society; specialist certified by the American Board of Orthopaedic Surgery, Inc.; served with the 149th Field Artillery in France during World War I; formerly an intern at St. Luke's Hospital in Chicago; past president of the Macon County Tuberculosis and Visiting Nurses' Association; on the staffs of the Decatur and Macon County and St. Mary's hospitals; died in Minoqua, Wis., August 7, aged 44, of coronary thrombosis.

Henry Carter Metcalf ♂ Connersville, Ind.; University of Louisville Medical Department, Louisville, Ky., 1913; served as a member and at the time of his death president of the Indiana State Board of Health; served as secretary of the Fayette County Board of Health, county coroner and president of the Fayette-Franklin Counties Medical Society; served overseas as a first lieutenant with the 163d Depot Brigade, 132d Engineers during World War I; member of the Connersville Board of Health; director of the Central State Bank; died in the Fayette Memorial Hospital, September 23, aged 56, of hypertensive vascular disease.

William Edwin Joiner, Seattle; Bellevue Hospital Medical College, New York, 1898; member of the Washington State Medical Association and the Pacific Coast Oto-Ophthalmological Society; served during World War I; lieutenant colonel, medical reserve corps, U. S. Army, not on active duty; for many years affiliated with the Veterans Administration; at one time served as assistant eye surgeon at the Brooklyn Eye and Ear Hospital, Brooklyn; died in the Veterans Administration Facility, Portland, Ore., August 7, aged 74, of bronchiogenic carcinoma.

John Robert Abercrombie ♂ Baltimore; University of Maryland School of Medicine, Baltimore, 1895; formerly associate professor of dermatology at his alma mater; served as professor of materia medica and dermatology at the Woman's Medical College of Baltimore; died August 3, aged 75.

George Sheldon Adams * Yankton, S. D.; Rush Medical College, Chicago, 1901; member of the American Psychiatric Association; medical superintendent of the Yankton State Hospital; on the staff of the Sacred Heart Hospital, where he died July 28, aged 67, of chronic endocarditis and acute dilatation of the heart.

James Tevis Arwine, Santa Rosa, Calif.; University of the South Medical Department, Sewanee, Tenn., 1894; member of the American Psychiatric Association; served during World War I; served on the staffs of various Veterans Administration facilities, including the one at Palo Alto, where he died August 24, aged 71, of arteriosclerotic heart disease.

Albra W. Baker, Elizabethtown, Pa.; State University of Iowa College of Homeopathic Medicine, Iowa City, 1887; died in the Masonic Home August 16, aged 85, of cerebral hemorrhage and arteriosclerosis.

William A. D. Barnhill, Laotto, Ind.; Cleveland Medical College, Homeopathic, 1893; died in the Methodist Hospital, Fort Wayne, September 25, aged 84, of pneumonia following a fracture of the left femur received in a fall.

Stephen Vincent Bedford, Jefferson City, Mo.; University of Missouri School of Medicine, Columbia, 1903; member of the Missouri State Medical Association; served as presi-

William King Campbell * Long Branch, N. J.; University of Pennsylvania Department of Medicine, Philadelphia, 1900; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; past president of the Monmouth County Medical Society; chief of the eye, ear, nose and throat department, Monmouth Memorial Hospital; vice president of the Long Branch Building and Loan Association; died September 21, aged 65, of coronary thrombosis.

Charles Leonard Christiernin * Maplewood, N. J.; Harvard Medical School, Boston, 1906; member of the Massachusetts Medical Society; in 1916 became assistant medical director and in 1935 medical director of the Metropolitan Life Insurance Company, New York; a member of the executive committee of the Association of Life Insurance Medical Directors, of which he had been treasurer, vice president and president; died suddenly October 18, aged 66, while on a vacation in Coreys, N. Y., of coronary thrombosis.

Francis Xavier Crawford, Boston; Harvard Medical School, Boston, 1898; member of the Massachusetts Medical Society, on the staffs of St. Elizabeth's and Carney hospitals; medical director for the United Fruit Company; died August 19, aged 71, of cerebral hemorrhage.

dent of the Cole County Medical Society; on the staff of St. Mary's Hospital; chief surgeon for the Missouri Pacific Railroad; died August 23, aged 63, of myocarditis and multiple neuritis.

Edison William Brown, Revere, Mass.; Tufts College Medical School, Boston, 1905; member of the Massachusetts Medical Society; on the staffs of the Winthrop Community Hospital, Winthrop, Whidden Memorial Hospital, Everett, and the Chelsea Memorial Hospital, Chelsea, where he died August 18, aged 67, of coronary thrombosis.

Emilio Deantonio * Scranton, Pa.; Regia Università degli Studi di Pavia Facoltà di Medicina e Chirurgia, Italy, 1894; in June 1944, presented with a testimonial plaque by the Medical Society of the State of Pennsylvania in recognition of fifty years of practice; formerly associated with the Scranton Private Hospital; died August 28, aged 72.

Bernard Walker Donohue, Baltimore; University of Maryland School of Medicine, College of Physicians and Surgeons, Baltimore, 1931; served an internship at the University of Maryland Hospital and the Bon Secours Hospital; served a

KILLED IN ACTION

William C. Craig, Waynesboro, Pa.; Ohio State University College of Medicine, Columbus, 1935; member of the Medical Society of the State of Pennsylvania, served an internship at the Allegheny General Hospital, Pittsburgh; commissioned a first lieutenant in the medical corps, Army of the United States, Sept. 4, 1942 and began active duty Oct. 15, 1942; a flight surgeon in the air corps; killed in action in the South Pacific area April 28, aged 33.

Tennysen Gates Johnson, Kerkhoven, Minn.; University of Minnesota Medical School, Minneapolis, 1943; served an internship at the City of Detroit Receiving Hospital, Detroit; commissioned a first lieutenant in the medical

corps, Army of the United States, on Aug. 6, 1942, began active duty on July 3, 1943, killed in action in the European area July 13, aged 28.

Bertram Wallace Morse, Whitcomb, Mich.; Detroit College of Medicine and Surgery, 1932; member of the Michigan State Medical Society; served an internship at the Henry Ford Hospital in Detroit; served as health officer and as vice president of the chamber of commerce; commissioned a captain in the medical corps, Army of the United States, on May 21, 1942; began active duty on June 22, 1942, later promoted to major, killed in action in the European area August 29, aged 43.

residency at the University Hospital, died August 19, aged 38, of bronchogenic carcinoma with metastasis

Lovie Culver Ellis, Florence, Ala., University of Tennessee College of Medicine, Memphis, 1914, member of the Medical Association of the State of Alabama, died September 22, aged 53, of coronary thrombosis

Charles Henry Herrick, Unadilla, N Y; Albany Medical College, Albany, N Y, 1893, member of the Medical Society of the State of New York, health officer of the village and town of Unadilla, formerly health officer of Gilbertsville, on the staff of the Sidney Hospital, Sidney, died in the Aurelia Osborn Fox Memorial Hospital, Onondaga, August 30, aged 80, of arteriosclerotic heart disease

George Inglis, Oswego, Ore., Rush Medical College, Chicago 1884, died August 28, aged 88, of arteriosclerosis and myocarditis

Roy Howard Johnson, Los Angeles; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1904, member of the California Medical Association; anesthetist at the Orthopaedic Hospital, member of the staff of the California Hospital, where he died July 24, aged 66, following a gastrectomy and virus pneumonia

Charles Warton Kidder, Woodstock, Vt., University of Vermont College of Medicine, Burlington 1907, served during World War I, died in the Veterans Administration Facility, White River Junction, August 6, aged 59, of cerebral hemorrhage

Franklin Jacob Lins, Durand, Ill., Rush Medical College, Chicago 1897, died in St. Anthony's Hospital, Rockford August 1, aged 80, of coronary sclerosis

Eugene Alphonsus McCabe, Sioux City, Iowa, John A. Creighton Medical College, Omaha, 1920, died August 21, aged 47, of coronary heart disease

William Adam Mess, Washington, D C., George Washington University School of Medicine, Washington 1907, also a pharmacist, medical examiner for Selective Service Board number 14, on the staffs of the Sibley, Doctors, Homeopathic, Providence, Garfield, Georgetown, George Washington and Emergency hospitals, killed in an automobile accident on the Mount Vernon Highway, Alexandria, Va., August 11, aged 62

Elmer Ewell Owen, Batavia, N Y., University of Michigan Homeopathic Medical School, Ann Arbor 1907, member of the Medical Society of the State of New York, served in France during World War I, died August 2, aged 62, of actinomycosis

Peter Marius Pedersen, Dannebrog, Neb., University of Nebraska College of Medicine, Omaha 1904, died August 2, aged 73, of heart disease

John Henry Reichling, Bennington, Vt., University of Vermont College of Medicine, Burlington 1906, on the staff of the Henry W. Putnam Memorial Hospital, died in St. Donat, Canada, September 18, aged 65, of cardiac syncope

Charles William Smith, Aliquippa, Pa., Western Pennsylvania Medical College, Pittsburgh, 1906, member of the Medical Society of the State of Pennsylvania, examining physician for draftees during World Wars I and II, served as president of the local board of health, died August 2, aged 66, of carcinoma of the left kidney

Arthur Gilman Tullar, North Hollywood, Calif., Northwestern University Medical School, Chicago, 1906, died October 11, aged 67, of coronary thrombosis

John David Vedder, Johnstown, N Y., Albany Medical College, Albany, N Y, 1896, member of the Medical Society of the State of New York, served as secretary, president and treasurer of the Fulton County Medical Society, formerly city health officer, city physician and member of the board of health, on the courtesy staff of the Nathan Littauer Hospital, Gloversville, died August 7, aged 81, of pyonephrosis

George Fritz Way, Urbana, Ill., University of Illinois College of Medicine, Chicago, 1911, died in the Wesley Memorial Hospital, Chicago, August 14, aged 59, of carcinoma of the rectosigmoid

Carl Frederick Weinberger, Chicago, Rush Medical College, Chicago, 1907, member of the Illinois State Medical Society, at one time principal of Muskegon High School, Muskegon, Mich., on the consulting staff, Evangelical Hospital, Chicago, where he died August 14, aged 71, of cerebral hemorrhage

Jacob Andrew Youngman, St. Louis, St. Louis College of Physicians and Surgeons, 1905, on the staff of St. Anthony's Hospital, died at his home in Sappington, Mo., August 10, aged 66, of coronary sclerosis and chronic myocarditis

DIED WHILE IN MILITARY SERVICE

John Weyman Davis, Athens, Ga., Emory University School of Medicine, Atlanta, 1927, member of the Medical Association of Georgia and the Southeastern Surgical Congress, fellow of the American College of Surgeons, on the surgical staffs of the Athens General and St. Mary's hospitals, commissioned a lieutenant commander in the medical corps of the U S Naval Reserve on Oct. 12, 1939, began active duty on May 19, 1941, promoted to commander on Aug. 1, 1942, died in the Naval Hospital, Charleston S C., September 18, aged 42, of Rocky Mountain spotted fever.

Frank John Fischer, Chagrin Falls, Ohio, University of Wisconsin Medical School, Madison 1934, formerly an intern and resident in surgery at the City Hospital and a resident in surgery at St. John's Hospital, both of Cleveland, fellow of the American College of Surgeons, served on the surgical staff of St. Luke's Hospital in Cleveland, certified as a commercial pilot by the Civilian Aeronautics Commission on July 1, 1942, commissioned a captain in the medical corps, Army of the United States, on Sept. 8, 1942, certified as an aviation medical examiner, stationed at the hospital, Camp Springs Army Air Field, Washington, D C., died September 21, aged 35, as the result of a plane crash following a forced landing 20 miles west of Leesburg, Va.

John Edward Fissel Jr., Newport News, Va., University of Maryland School of Medicine, College of Physicians and Surgeons, Baltimore, 1936, formerly secretary and treasurer of the Warwick County Medical Society, served an internship at the Church Home and Infirmary in Baltimore and a residency in surgery at the Riverside Hospital, commissioned a first lieutenant in the medical reserve corps of the U S Army on Sept. 7, 1942, later promoted to captain, killed in Prestewick, Scotland, August 22, aged 32, in an airplane accident

Frederick Hugh Greenwell, Lieutenant (jg) M C U S Navy, New Haven, Conn., University of Louisville (Ky.) School of Medicine, 1943, intern at the Naval Hospital, Jacksonville, Fla., where he died August 10, aged 27, of primary atypical pneumonia

George Bernhard Miller, San Francisco, Stanford University School of Medicine, San Francisco, 1935, served an internship and residency at the Lane and Stanford University Hospitals and a residency in tuberculosis at the San Francisco Hospital, commissioned a first lieutenant in the medical corps, Army of the United States on Nov. 11, 1942, died in Grass Valley, July 15, aged 34, of myocardial infarction due to coronary disease

Woodman Bradbury Pomeroy, Lieutenant, M C, U S Navy, Pittsburgh; Harvard Medical School, Boston 1941, served an internship at the Pittsburgh Medical Center, commissioned a lieutenant (jg) in the medical corps U S Navy, on July 14, 1942, promoted to lieutenant on May 1, 1943, flight surgeon, died in the Pacific area July 12, aged 28, of extensive multiple injuries

Stephen William Smith Jr., Hamden, Conn., Tufts College Medical School, Boston 1940, served an internship at the Memorial Hospital in Worcester, Mass., diplomate of the National Board of Medical Examiners, commissioned a lieutenant (jg), medical corps U S Naval Reserve on Nov. 4, 1941, later assigned to the destroyer U S S *Ingham*, promoted to lieutenant on June 15, 1942, aged 28, presumptive date of death at sea in the Atlantic area Aug. 23, 1943, according to the Navy Department

Jerome Daniel Solomon, Chicago, University of Illinois College of Medicine, Chicago, 1941, served an internship at the Cook County Hospital, commissioned a first lieutenant in the medical reserve corps of the U S Army on June 6, 1941, began active duty on Sept. 21, 1942, later promoted to captain, died in the Southwest Pacific area September 16, aged 28, of tsutsugamushi fever and malaria

John Wesley Speake Jr., Spartanburg, S C., Medical College of the State of South Carolina, Charleston, 1936, served an internship at the Spartanburg General Hospital, commissioned a first lieutenant in the medical corps, Army of the United States, on Aug. 12, 1942, later promoted to captain, a flight surgeon, killed in the European area July 28 in an airplane accident, aged 34

Bureau of Investigation

ADVENTURES OF A DODGER

"Oh Boy!" Perry's Scheme Declared a Mail-Order Fraud

Many of those who dispense health hokum to a credulous public might prosper indefinitely in their enterprises, did not a skeptical Post Office Department look into their schemes and scotch them with fraud orders. Such was the case of Victor Edison Perry of Philadelphia, who carried the letters ND after his name, indicating that he is either a naturopath or a naprapath.

In January 1943 the Post Office Department cited Perry to appear at a hearing and show cause why his business should not be debarred from the mails on the charge that it was a scheme to obtain money through the sale of "GEN SEN" under fraudulent representations that it was an effective treatment for arthritis, diabetes, asthma, liver, kidney, bladder and stomach disorders, and some other ailments. Perry then signed an affidavit that his business had been absolutely discontinued and would not be resumed at any time under any name. This affidavit, he admitted, was filed for the purpose of obviating future fraud order proceedings. In it he agreed to acquiesce to such fraud order if he should be found to have violated his promise. And violate it he did. He continued his business, substituting the names "Vita" and "Nu Vita" for the old one, "GEN SEN," adopting the new trade styles "Vita Herbs Company," "Nu-Vita Herbs Company" and "V E Perry" and using New York and Philadelphia addresses. Soon afterward he executed another affidavit for the Post Office Department in which he admitted that he had resumed the sale of his nostrum under the aforesaid new names thus violating the earlier affidavit. In this second one he again declared that his enterprise had been absolutely discontinued and would not be resumed. In November 1943 however, the Post Office Department cited him again to show cause why a fraud order should not be issued against him. The outcome of the hearing will be mentioned later.

Perry's penchant for alliteration in calling certain of his later nostrums 'Perry's Peptone Pep Pills,' "Peptone Perry's Pink Pep Pills" and "Perry's Famous Peptone (Spanish Fly) Pep Pink Pills" recalls another medicaster's "Pink Pills for Pale People." As the names indicated the various "Pep Pills" were promoted for sexual weakness. Another Perry nostrum "Natura," was represented as a cure for rheumatism, catarrh, low or high blood pressure, swollen tonsils and many other disorders. Perry advertised all his nostrums in their time through periodicals of local and national circulation. What he formerly sold as GEN SEN was played up as "God's gift to India and India's gift to you" and also as "India's Famous Herb Tea." It consisted of three units which were contained, respectively, in red, white and blue packages carrying the American flag (an apparent violation of law), and prospective customers received return envelopes addressed to Perry, on which he spelled his first name "Victory." Some of his advertising literature carried a large red heart on which was printed in white "Is your wife still your sweetheart? Try GEN SEN."

The advertising of Natura instead of representing the product as being from India, described it as a 'Mexico herb tea,' and this literature, too, was done in red white and blue. If one could believe the claims, it was the 'World's Greatest Spring Tonic' and would help "hubby and yourself over 30 feel like 'Sweet Sixteen.' Oh Boy!" Besides it was touted as a reducer under the slogan "It's so easy to be streamline, with Natura."

This "streamliner" according to a government chemist who testified at the Post Office hearing contained sulfur, epsom salt sodium bicarbonate senna cascara and licorice and was identical with GEN SEN. Perry's Peptone Pep Pills, the witness said were essentially a mixture of gentian phosphorus strychnine columbin iodine, cantharides and U S P thyroid. None of the ingredients named for the two preparations constituted anything original or unfamiliar, as was pointed out by another government witness, a Senior Medical Officer of the Food and Drug Administration, nor would such mixtures have any par-

ticularly beneficial effect on the ailments for which these were advertised. He showed that they would not purify the blood or restore the user to a 'new life of youth and pep,' nor would Natura be of any value whatever in treating obesity. As for impotence he testified, the only proper treatment for this would have to be based on a careful diagnosis to ascertain the type and cause of the condition, which in some cases might be psychic.

At this hearing Perry offered no medical witness but, when given opportunity to present his case, devoted practically all his time to asserting that the use of his preparations had given him the vigorous health that was his despite his seventy-seven years. The charges against him were sustained by the evidence presented, and on May 12 1941 a fraud order was issued, covering the names Victor Edison Perry Victory Edison Perry and the numerous variations that he used.

Reproduced on this page is the cartoon front of another Perry nostrum apparently a supplementary laxative 'Natura (Ovato Seeds)' (On another side of the cartoon is the claim 'Ovato Seeds' from Mother Earth—Contains the 16 Elements of Health,' and the further boast "Prominent M.D.'s all over also Metropolitan Life Insurance Co N Y Life Extension Institute and U S Government recommend it very highly.") The package also bears the name of the National Health University (whatever that may be) designating Perry as its president and giving addresses in New York, Boston and Worcester, Mass. besides mentioning 'Operating 23 Founts of Youth Pep Beauty Health Success in U S A.' Possibly one of the "Founts" was "Dr. Perry's Famous Water Crystal and Mineral Salt Hotel and Baths," which, a report said, he was once operating in Beaumont, Texas. The same report stated that his National Health University had its main 'laboratory' at Burbank, Calif., and that Perry gave 'lectures' to promote the sale of many types of alleged health foods.

Apparently the activities of Victor Edison Perry, national dispenser of health can best be summarized by a term in his own advertising—"Oh Boy!" But he is now seventy-seven years old and if Post Office fraud orders won't stop him, the biologic life cycle probably will.

MALIGNANT GROWTH AFTER SINGLE TRAUMA

To the Editor:—As a contribution toward the solution of the problem raised by correspondents in *THE JOURNAL*, September 9 and 16, concerning the possibility of a malignant growth resulting from a single trauma, I submit the following case report. Please note that it is based on the sworn testimony of physicians and others having personal knowledge of the facts of the case reported:

In April 1935, about 11 p. m., in Salina, Kan., Parker, in the course of his employment, was carrying a box of books. He stumbled, the box struck and damaged the top of a desk, and Parker's chest struck the box. Before quitting work, about 1 a. m., Parker left a note for his supervisor reporting the incident. Whether he reported at that time that he had been hurt is not clear, but when he reached home shortly after 1 o'clock he told his wife of the accident and that his chest had struck the box and was hurting. There was no evidence that he had up to that time suffered from any chest pain. His wife did not examine his chest until three or four weeks later. Then she found "a red spot" about the size of a dollar. On May 15 Parker consulted a physician. About the same time—possibly a month or six weeks or possibly two months after the accident—he told his supervisor that he had hurt his chest when he fell with the box of books and that "a bump" on his chest was caused by a bump or a bruise. Two weeks later, admittedly six weeks to two months after the accident, he showed his supervisor "the swelling" and told him that he got it when he dropped the box about two months previously. Parker continued at work for about fourteen months, although under the care of a physician, Dr. Jenney. By June 16, 1936 the tumor had grown to a lump "the size of a baby's head." It was then removed by an operation. Thereafter Parker was confined to his bed until his death, Sept. 16, 1936.

In proceedings by Parker's widow under the workmen's compensation act, four physicians testified. Dr. Jenney, who had treated Parker from about three weeks after his injury until the time of his death, testified that when Parker first came to his office he had "a hard protuberance, tumor-like" and that he, Jenney, believed that the fall and hurt of which Parker told him was the cause of the injury that eventually developed into the sarcoma of the breastbone. Dr. Fitzpatrick, who had taken x-ray pictures of Parker's chest in March 1936, testified that they revealed a growth on the chest and bone, destruction of the sternum and cartilage of the ribs in the front of the chest; he gave it as his professional opinion that Parker's condition could have possibly come from the alleged injury to his chest in 1935. Dr. Mowery, who removed the growth, gave it as his professional opinion that the tumor resulted from the injury. Dr. Seit, an expert called not by the claimant but by the respondent, testified that sarcoma malignancies are not traceable to trauma in more than two percent of the cases, or even less, but he added:

The important thing is the establishment of the fact of a trauma, and finding within this tissue or that immediately adjacent to the . . . periosteum and the structure of the bone or immediately adjacent to the point of the alleged injury, evidence of the injury. If in such a tissue anywhere from four weeks to a year, or even more, a malignancy develops, I believe it would be considered due to the trauma.

The foregoing clinical history is summarized from a decision of the Supreme Court of Kansas, Dec. 11, 1937, in *Parker, appellee, v. The Farmers Union Mutual Insurance Company and The Maryland Casualty Company*, 146 Kan. 832 (73 P. 2d, 1032). In summarizing the evidence, the court said:

... shall this court say that Parker's prompt report to Cameron, his superior, about his tripping and falling with the box of books, his later statement to Cameron that he hurt his chest in the same fall, the rapid growth of the malignant tumor on his breastbone and the professional opinions of the doctors that such a malignant growth was probably due to the injury as narrated by Parker—all these evidential matters, including the pertinent circumstances, were not sufficient to establish the fact of the accident and the injury? How could the evidence be stronger?

Was not the injury described the exciting cause of the sarcoma that followed? Before denying a causative relation one should point out some reasonably likely cause other than the injury. Before attributing the entire incident to the so-called laws of chance, one should consider the incidence rates of sarcomas of the sternum and of contusions of the sternum on the entire population and then estimate the chances of the occurrence of such a contusion and such a sarcoma coincidentally in site and in immediately chronological sequence. If it be admitted that a contusion has ever caused a sarcoma of the sternum, what ground is there for believing that other traumas may not cause other malignant growths? The relation between malignant growths and cleancut incised wounds and punctured wounds made with sharp instruments may merit separate consideration, for I cannot recall ever seeing a report of a claim for compensation based on the occurrence of a malignant growth as the result of such an injury. Even so, one must not overlook the etiology of keloids, sometimes attributed to even such trauma.

A large financial interest is involved in the problem here discussed. An employee who suffers from a malignant growth caused by a trauma arising out of and in the course of his employment is in most jurisdictions, if not in all, entitled by law to compensation for the injury, to be paid by the employer by whom he was employed when the injury was received. The presence of such a growth at the site of the injury cannot enter into the determination of compensation if the element of causation is not proved. Proof need not be conclusive or beyond a reasonable doubt. The award is made according to the preponderance of the weight of the evidence submitted by employee and employer. If a single trauma can never by any possibility cause a malignant growth, however, every award in favor of the employee in such a case obviously imposes an injustice on the employer, no matter what the weight of the evidence may be.

To prevent such injustice it has been urged that the dictum which denies the possibility of a causative relation between any single trauma and a malignant growth subsequently appearing on the site of that trauma be generally accepted. The universal acceptance of that dictum would go a long way toward preventing such injustice. But might it not give rise to injustice equally extensive and even more grave? It would certainly tend to deter injured workmen from filing claims based on such injuries and growths, hinder lawyers in the prosecution of such claims, embarrass physicians, regardless of their own studies, experience and observation, sought as witnesses in support of such claims, and operate, subconsciously or otherwise, to warp the judgments of boards, commissions and courts required to pass judgment. For possible injustice to individual employers, the adoption of the dictum of noncausation would substitute certain mass injustice to many employees, if it should prove unfounded, as the case stated at the beginning of this communication indicates that it is. And by the time the fallacy of the dictum was demonstrated many employees, and many persons in other walks of life who but for it might have sought damages for injuries suffered at the hands of others, will have lost their rights to redress, through the limitations of time for presenting their claims fixed by the workmen's compensation acts and statutes of limitation and through the disappearance of essential witnesses.

Have biology and medical science already determined the causes of malignant growths in the human body so certainly as to call for affirmative action to cause the adoption universally of the dictum that no single trauma ever has caused a malignant growth or ever can do so? Do available records indicate that under existing medical and legal procedure so many employers are being unjustly required to pay compensation for malignant growths due to single traumas as to require a revision of medi-

cal opinion with respect to the cause or causes of such growths? If neither of these questions can be answered in the affirmative, why not wait for further evidence as to the causes that operate to produce such growths before undertaking to reform medical opinion? WILLIAM C. WOODWARD, M.D., Washington, D. C.

"YAWS, CUTANEOUS LEISHMANIASIS AND PINTA"

To the Editors:—With reference to Dr. Howard Fox's communication (THE JOURNAL, April 8) replying to my comments (March 4) regarding his article "Yaws, Cutaneous Leishmaniasis and Pinta" (THE JOURNAL, Oct. 23, 1943) I should like to point out:

1. If an incidence of 4 per cent of the macular rash of yaws is considered "the equivalent of being nearly always absent," then we are in agreement as to this type of lesion. As the macular rash appears early in the course of the disease its incidence should be calculated on the total number of lesions of all types seen in persons with a history duration of one year or less. My calculations on this basis gave an incidence of 6.5 per cent. Either figure (4 or 6.5 per cent) seems to me significant, particularly as in some cases there may be only a few macules and the tendency is for them to disappear early—perhaps before the patient comes up for examination. For purposes of comparison I should be glad to know what, in the experience of others, is the incidence of the roseola rash of syphilis.

2. In support of his statement "In the early stages the disease may be permanently cured by three successive injections of neoarsphenamine," Dr. Fox mentions the results of Morse, quoted by Strong, on 1,064 cases treated in Santo Domingo (in my edition Stitt Moss is quoted) and revisited after five years. Moss (again in my edition) found that 46.5 per cent of the cases reexamined—i. e., 419—remained uncured. He also quotes Strong to the effect that in the Philippines with two injections as the rule 94.3 per cent of clinical cures resulted. No mention is made of the period over which these cases in the Philippines were followed up or if by the term "clinical cure" a temporary clearing up only of the lesions is meant.

I quoted in my previous article the percentages of persistent positive Wassermann reactions at six, twelve and eighteen months in a series of 411 cases in which six successive injections of neoarsphenamine had been administered. I should have added that it was from these persistent positive reactions the relapsing lesions developed; that infectious relapsing lesions were more frequent during the first year following treatment of early cases than in the second or subsequent years; that environmental and climatic conditions were major factors in determining the time and percentage of relapses (consequently patients should be revisited in their districts toward the end of the rainy seasons to determine the real effects of treatment—an important point).

In a small series of 209 persons treated with four to six injections of neoarsphenamine (average 5.5 injections per patient) and revisited at six, twelve, eighteen and twenty-four months later, 28 had relapsing lesions (6 after six months, 7 after twelve, 9 after eighteen and 6 after twenty-four), a percentage of 13.4 relapsing cases. This percentage was found to be still higher for patients receiving one to three injections. Cases may relapse repeatedly in spite of an additional two to three injections after each relapse. The figure 28 represents the number of first relapses; further relapses are not included.

On the other hand, before an estimate can be made of the results of treatment there should be a clear picture as to the course of the disease in cases in which treatment has never been given. In Jamaica active lesions attributable to yaws are quite rare in patients who give a history of yaws of thirty or more years' duration.

Moss revisited his 1,064 patients in Santo Domingo after a period of five years. In two areas in Jamaica 1,520 persons with a history of yaws of five years upward who maintained that they had never had treatment by injections were seen and 1,424, or 93.65 per cent, showed no clinical evidence of active yaws; only 96, or 6.64 per cent, had such evidence. In these same areas 467 patients gave a history of yaws of four years or less without receiving treatment; 308, or 65.95 per cent, had active yaws lesions; 159, or 34.05 per cent, had no active lesions.

My contention is that specific treatment early in the course of the disease is of value primarily in limiting the spread of the disease in any community where environmental conditions cannot be speedily improved. Such treatment (even with six or more injections) does not necessarily indicate that the disease is cured. I would suggest that to regard the absence of physical lesions as evidence of cure is no more logical than to do so in cases of syphilis.

It would be comparatively easy to clear endemic areas of yaws if one to three injections could cure the disease. The fact is that there will always be some cases of relapsing infectious lesions from which a further spread of the disease by contagion is possible.

H. D. CHAMBERS, M.D.,
General Hospital,
Kingston, Jamaica.

[The letter was referred to Dr. Fox, who replies:]

1. Dr. Chambers has made it appear that I considered a 4 per cent incidence of the macular eruption to be the equivalent of being "nearly always absent." In my answer to his communication in THE JOURNAL, April 8, I distinctly said that only one author had observed such an incidence. All others of long experience with yaws either failed to mention a macular eruption or definitely said that it did not occur in yaws.

2. The statement quoted from Colonel Strong was to the effect that in the early stages the disease *may* (italics mine) be permanently cured by three successive injections of neoarsphenamine. This would not mean that such a result was always bound to occur.

Dr. Chambers said that in his own series of 209 cases treated by an average of 5.5 injections of neoarsphenamine he found 13.4 per cent of relapses after periods of observation varying from six to twenty-four months. The freedom from relapse in 86.6 per cent of his cases supports my opinion of the curability of yaws in the early stages, certainly when compared with the curability of syphilis.

HOWARD FOX, M.D., New York.

PRIZE WINNING MONOGRAPHS IN BRAZIL

To the Editor:—In THE JOURNAL, May 6, a mistake was noted in the letter from Brazil. The monographs are in error, since separate competitions were entered during the year, and the following is a correct listing of the prize winning monographs:

1. "History of Leprosy in Brazil and the Geographic Distribution of the Disease," by Flavio Maurano.
2. "Etiology and Pathology of Leprosy," by Abrahão Rotberg and Luiz Marino Bechelli.
3. "Epidemiology and Control of Leprosy," by Nelson Sousa Campos, Abrahão Rotberg and Luiz Marino Bechelli.
4. "Clinic and Therapeutic of Leprosy," by Luiz Marino Bechelli, Abrahão Rotberg and Flavio Maurano.

LUIZ MARINO BECHELLI, M.D.,
Post-Graduate Medical Hospital,
New York.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Medical Practice Acts: Conviction of Limited Practitioner for Exceeding the Scope of His License.—The Bureau of Medical Education and Licensure of Pennsylvania¹ in 1915 issued a limited license to Allison which conferred on him "the right to treat the sick by Herbs and Massage . . . upon request of a person duly authorized to prescribe the same." Twice previous to the institution of the action here involved he was convicted of having exceeded the authority granted him by this license and of engaging in the practice of medicine and surgery. Both convictions were upheld by the superior court of Pennsylvania. *Commonwealth v. Allison*, 103 Pa. Superior 140, 156 A. 812; *id.* 132 Pa. Superior 606, 1 A. (2d) 920. Again, in the case here abstracted, he was indicted for and convicted of exceeding the scope of his limited license and engaging in the practice of medicine and surgery without restriction. He appealed to the superior court of Pennsylvania.

Either Allison, said the superior court, has no respect for the law or he is mentally incapable of understanding the limitations implicit in the form of license he possesses. For not only did the prosecution show that, at the times charged in the indictment, he accepted patients, examined them, diagnosed their ailments and prescribed treatments; he glibly admitted these practices from the witness stand. And there is not even the pretense that he limited his patients to those referred for treatment by a properly licensed physician; in fact, one has the impression from reading his testimony that he regards all orthodox physicians as either fools or knaves and will have little or nothing to do with them. Having twice appealed to us in vain one would expect that in this, his third, appeal the ingenuity of counsel, challenged by almost overwhelming odds, would produce a somewhat novel approach to the problem. We have not been disappointed. Allison now contends that, in restricting him to the treatment of patients referred to him by licensed physicians, the licensing agency—composed, according to him, of "professional competitors"—has arbitrarily discriminated against him; that there is no statutory authority in Pennsylvania for such a narrow limitation on his authority and that the limitation contravenes the Fourteenth Amendment to the Federal Constitution.

True, continued the court, there is no express statutory authority for the particular limitation complained of by Allison. The Pennsylvania medical practice act gives the bureau broad, discretionary powers to establish a system of special licensure and to issue to persons who fulfil such special qualifications as the bureau provides a license to practice one or more of the limited branches of medicine or surgery. The constitutionality of this provision was upheld in *Long v. Metzger*, 301 Pa. 449, 152 A. 572. Of necessity the bureau may make discriminations; they are inherent in the nature of the functions it performs. Yet we must grant that the acts of the bureau may always be subjected, by one affected, to the test of reasonableness under the Fourteenth Amendment. But, so far from being unreasonable, the requirement imposed by the bureau that practitioners of this kind should treat patients only at the request of, and hence under some supervision by, a licensed physician is a necessity if the public is to be protected adequately against exploitation.

Allison, continued the superior court, is a quack of the worst sort. It is easy to see why, if he were compelled to wait for

patients referred to him, by physicians, he would have no practice. At the trial there was no proof of the chemical ingredients of the pills and nostrums he sold to his patients nor the type of massage he employed. But the miracles he professed to be able to accomplish would make the witchery of the Middle Ages seem by comparison an infant and underdeveloped craft. He professes to be a "bloodless surgeon, a botanic physician." When asked how he would cure a case of appendicitis he said:

That is very easy. That would be cured in one hour's time ordinarily without shedding any blood or making any incision or like that. That is easily cured in one hour and a patient is ready to go to work in one hour.

When asked what he would do with ruptured appendix, he said:

Why, my friend, I have been practicing forty-three years and I have yet to see the physician that has ever saw [sic] a ruptured appendix.

He could remove diseased tonsils without cutting:

By the use of herbs taken internally and massage to the throat, cure any case of tonsils, just—well, I'll say within a week or so.

He professed to have cured many cases of cancer, and as for paralysis:

Often times paralysis is caused by an obstruction of circulation and by removing that obstruction in a few minutes time the party has the full use of their arms or legs.

It makes one shudder, continued the court, to think that a man like this should be entrusted with any part of the responsibility for the diagnosis or treatment of human disease. The story of this case is more persuasive than any abstract argument could possibly be of the wisdom of the bureau in limiting such practitioners to treatments requested by licensed physicians.

Accordingly, the judgment of conviction was affirmed.—*Commonwealth v. Allison*, 38 A. (2d) 535 (Pa., 1944).

AMERICAN BOARD OF RADIOLOGY: Oral. New York, June 3. Final date for filing application is May 1. Sec., Dr. B. R. Kirklin, 102-110 Second Ave. S.W., Rochester, Minn.

1. Now officially designated as the State Board of Medical Education and Licensure.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1934 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Management and Prognosis of Megacolon (Hirschsprung's Disease).—Grimson and his co-workers review the records of patients with megacolon seen since the opening of Duke clinic in 1930. The present status of the patients has been determined by correspondence and by return visits. Of 24 patients with megacolon, 21 were treated by conventional medical management, consisting chiefly of diet, laxatives, enemas and parasympathomimetics, occasionally supplemented by sympathectomy. Three of the 21 patients required emergency laparotomy. A severe fecal impaction was removed in 1. Volvulus of the sigmoid colon was reduced in 2. Six of the 21 patients have undergone a remission of symptoms without surgical intervention. One patient underwent a remission of symptoms after sympathectomy and is well at the age of 17. Seven have continued to have mild to severe symptoms and at an average age of 15 are receiving medical treatment. Five patients, including 1 of the 3 who had a laparotomy, have died. The remaining 3 of the 24 patients presented alarming symptoms and were treated by one stage resection of the megacolon and ileosigmoidostomy. These 3 are now living and well. Medical management was supplemented by sympathectomy for 4 of the 24 patients. The gross pathologic picture was not significantly altered. One sympathectomized patient improved and is living and well at the age of 17. Another improved for three years and then died at the age of 24 with an acute impaction and perforation of the colon. Two others experienced difficulty after sympathectomy. The initial observations indicate three types of involvement of the colon, and the follow-up studies warrant classification of the 24 patients into three groups. The first group, of 12 patients, had uniform involvement of the entire colon terminating in a dilated or easily dilatable rectum. Eight are now living and evacuating their colons readily. It appears that protracted medical management of patients in this group is indicated as long as adequate nutrition can be maintained and persistent abdominal distention avoided. The 7 patients of group 2 had uniform dilatation of the proximal segments of colon terminating in a normal segment of bowel, usually in the sigmoid region, and a normal rectum. Four receiving conventional management died. The remaining 3, with enormous megacolons, were treated by resection of the megacolon and anastomosis between the terminal portion of the ileum and the remaining stump of normal sigmoid colon. These 3 are living and well. Patients in this group demonstrated greater abdominal enlargement than the other patients. The third group comprised 5 patients who had enormous enlargement of the sigmoid colon or of the sigmoid and descending colon, with or without involvement of the proximal portions of the colon and of the rectum. The 5 are now living. Two free from symptoms and 3 with moderately severe symptoms. It seems that protracted medical management of patients in this group is justified.

Intensive Chemotherapy of Early Syphilis.—The treatment routine used by Neilson and his collaborators at Isolation Hospital in St. Louis was that devised by Chargin; 240 mg of mapharsen was given daily for five consecutive days, totaling 1,200 mg. The daily dose of drug was given in 2,000 cc of 5 per cent glucose solution dripped intravenously over a twelve hour period. Because fatalities resulted in small persons, the total dose for persons weighing less than 125 pounds (57 Kg.) was reduced to 900 mg. The 5 per cent glucose solution was later replaced by a 10 per cent solution, and the daily administration time was reduced from twelve hours to eight hours. Intensive therapy was completed 502 times on 487 patients. A few individuals were rejected because of a history of sensitivity to arsenic. In over one half of the cases insoluble bismuth was given in an attempt to create a chemotherapeutic regimen of maximum effectiveness. The authors describe and evaluate early and delayed reactions and discuss the 4 fatalities. Thirty-seven per cent of the first 414 patients receiving intensive therapy failed to make a single contact with the follow-up clinic. The time interval between treatment and the achievement of a negative Kahn test averaged 4.3 months in the group receiving mapharsen alone and 2.8 months in the group that received a bismuth compound in addition to mapharsen. Fifteen per cent of all patients followed for five months or longer developed serologic or mucocutaneous relapse. Many of these were given a second course of intensive treatment. Twenty pregnant women were treated and 17 were followed until delivery had occurred. Only 2 infants had definite congenital syphilis, and 2 babies had positive Kahn reactions. The follow-up of treated patients has not yet been long enough for a proper evaluation of the results. The authors believe that the rate of complete cure will not be less than 70 per cent.

March Fracture.—Hullinger and Tyler observed at Camp Wheeler 300 patients with 313 march fractures. Each patient showed either a fracture line or callus formation by x-ray examination. An additional large number of patients were seen who had many of the earlier signs of march fracture but never positive x-ray signs. There were about 450 patients in this group. The incidence of march fractures at this camp greatly increased beginning in March 1942, as a result of a training order issued in February, which stated that all trainees would carry rifles and full packs at all times during the training program, that the men would march by foot from one area to another instead of riding, and that they would move to adjacent areas frequently on the double time. This increased the admission to the hospital for march fractures to a peak of 66 for the month of May. On May 24 a memorandum was issued lessening the strenuousness of the training program, with the result that the number of cases fell off in June to 44 and in July to 17. While this type of fracture has been reported as occurring in the tibia, fibula, femur, calcaneus, pelvis and cuneiform, it is most frequently found in the second and third metatarsal bones. Prior civilian occupation may be a mild contributory factor in causing early fatigue. The weight of patients and their age do not seem to be contributory. The mechanism of fracture and healing would seem to be as follows: Because of the repeated minimal trauma, there is an incomplete fracture of a few of the bony trabeculations of the shaft, which is most often not visible on x-ray examination. This is followed by hemorrhage, which, being on the surface, produces an elevation of the periosteum. New bone is formed in the hematoma. Calcium deposits are seen in this area at an early date. If the trauma continues there is fracture of additional bone trabeculations and additional hemorrhage, further elevating the periosteum and giving rise to additional osteogenesis. There is then slight absorption of calcium at the fracture ends with the dehiscence becoming visible by x-ray examination. If the trauma ceases, the fracture proceeds to orderly healing with complete repair. Treatment should be complete immobilization to prevent motion at the fracture site. Complications are very few in cases treated by complete immobilization.

Colorado Tick Fever.—Collins states that cases of Colorado tick fever were encountered in May and June 1943 at Camp Carson Station Hospital. Thirty-nine men became ill with fever, chills, headache and myalgia lasting from one to two days, followed two days later by a relapse of similar character. A leukopenia was an almost constant finding. All of the men had sojourned in tick country, and the majority gave a history of being bitten by ticks. All were between the ages of 20 and 40, in supposedly good health until the present illness. In every instance a history was obtained of having bivouacked for several days in the vicinity of Lake George, near Colorado Springs, a region notorious for the number of ticks found there. All ticks removed in the hospital from these patients were identified as *Dermacentor andersoni*. Therapy was symptomatic, although sulfonamide drugs were used in 6 cases without noticeable benefit. Salicylates and codeine relieved the myalgia and headache to a large extent, and dehydration was combated by copious fluid, given intravenously when necessary. Laboratory facilities to investigate the cause further were lacking. Attempts to reproduce the disease in laboratory animals by others have been unsuccessful and the etiologic agent is as yet unknown.

Meningococcemia.—Ochs and his associates report that 6 cases of chronic meningococcemia without accompanying meningitis were recognized from a station hospital in this country during and following an outbreak of meningococcic meningitis. Chronic meningococcemia is characterized by irregular fever, arthralgias, myalgias and a skin eruption, the most characteristic lesion being a rose colored macule with a vesicular, pustular or petechial center of pinhead size. The diagnosis of meningococcemia can be suspected on clinical findings, but to the laboratory falls the responsibility of demonstrating the causative agent. Blood cultures for growing meningococci are more often positive if the blood is drawn when the temperature is rising or at its peak. Attempts to isolate organisms from the skin lesions were unsuccessful. Acute fulminating meningococcemia with or without meningitis is another form of meningococcic infection. Nine cases of this form have appeared at the authors' hospital during 1942, 1943 and 1944. One patient died suddenly before the disease was recognized, and 1 patient died suddenly twelve hours after treatment from pulmonary edema. The disease is so fulminating that one cannot wait for a confirmatory blood culture before instituting treatment. At present any patient showing a diffuse petechial, purpuric or macular rash, early coma or manifest restlessness with a leukocytosis is considered to have fulminating meningococcic septicemia. The blood culture is usually positive for meningococci. In 4 patients the diagnosis was immediately confirmed by demonstrating gram negative diplococci in a film of tissue juice obtained by cutting into a petechia. The authors were unable to determine the presence of hemorrhage into the adrenal glands. Although the clinical course of this disease is similar to the Waterhouse-Friderichsen syndrome, the authors have not diagnosed their cases as such. The histories of 3 patients with acute fulminating meningococcemia are described. The treatment of the fulminating cases is with one-sixth molar sodium lactate solution in isotonic solution of sodium chloride; sodium sulfadiazine intravenously and intramuscularly; adrenal cortex extract intravenously and intramuscularly; meningococcus antitoxin intravenously; 5 per cent glucose and saline solution intravenously; sodium citrate given with sulfadiazine orally; oxygen; recording of blood pressure, pulse, pulmonary signs for pulmonary edema and urinary output every two or three hours.

Sulfadiazine Prophylaxis of Acute Infectious Diseases.—Warren reports experiences in the use of sulfadiazine in controlling both sick call and hospital admissions from acute infectious diseases in more than 9,000 men at the Army Air Forces Technical Training School, Trux Field, Madison, Wis. This study was conducted as a part of the Army Air Forces Rheumatic Fever Control Program. Sulfadiazine in a prophylactic dosage of 3 Gm. once weekly proved ineffective in reducing the incidence of acute infectious disease among a group of 140 soldiers, but in prophylactic doses of 1 Gm. daily it effectively reduced the incidence of certain acute infectious diseases among 9,000 soldiers. This effect was evident both on admissions to the outpatient department and on hospital admissions for acute infectious diseases. Diseases caused by beta hemolytic streptococci, scarlet fever and nasopharyngitis due to streptococci were most effectively influenced. A definite effect was also apparent on the incidence of rheumatic fever occurring at a later period than the effect on acute hemolytic streptococcus disease. There was no effect on diseases caused by virus infection or of unknown etiology under this method of prophylaxis. Among 9,000 men, only 34 toxic reactions were encountered, and none of them were serious.

- Cadmium Poisoning.**—According to Spolyar and his associates cadmium poisoning in industry occurs from the accidental absorption of fumes or dust by way of the respiratory tract, seldom by ingestion. A symptom complex develops that is primarily referable to the respiratory tract and is manifested within four to eight hours by irritation of the nasopharynx, cough, headache and a metallic taste in the mouth. This is followed by a latent period of twenty to thirty-six hours, when the chief complaints are dyspnea and severe pain in the chest. Gastrointestinal complaints may develop, depending on the amount of cadmium swallowed. Cadmium poisoning by ingestion is usually manifested by symptoms referable to the gastrointestinal tract, namely persistent vomiting for a period of four to six hours with or without diarrhea. Cadmium, being a powerful emetic, seldom produces death when taken orally. This dual symptom complex may explain the scarcity of reported cases of cadmium poisoning occurring as a result of inhaling cadmium fumes or dusts, in that the gastrointestinal symptoms may have been looked for and were missing. The authors report the histories of 5 men who worked in a shop for flanging steel inlet pipes. Flanging was accomplished by a team consisting of two men, one known as the heater and the other as the flanger. The heater heated one end of the 6 inch pipe by means of a propane-oxygen blowtorch until it was cherry red. The flanger created a flange, or bevel, on the heated end of the pipe. This work had been done for six months, when a different type of pipe was supplied. Soon after beginning work, the men noticed more smoke than usual and a dense yellowish brown fume being emitted from the pipe. After all the 5 men who had worked on these pipes for about four hours each had become ill, the operation was discontinued. Death of 1 of these men, who had been longer exposed to the cadmium fumes, led to inquiry by the insurance company, which disclosed that the pipe was coated with cadmium. The authors present data on 38 additional cases of cadmium poisoning by inhalation. Of the total of 43 cases 6 were fatal, indicating a mortality rate of 14 per cent. Death occurs between the fifth and seventh day after exposure. Recovery occurs within seven to eleven days.

- Plasma, Whole Blood and Human Serum Albumin.**—Kendrick states that recent developments in the field of replacement fluids have not removed the necessity for whole blood transfusions. Whereas plasma and albumin are effective therapeutic agents in shock and burns, whole blood is still indicated in severe hemorrhage, secondary anemia from burns, infections, carbon monoxide poisoning and many medical diseases. Fresh whole blood and stored blood are used. In order to make fresh blood available in the "theater of operations," the distilled water bottle from the Standard Army-Navy Plasma Package will be salvaged and utilized. It may be necessary to have stored whole blood on hand for immediate use. Equipment will be provided in large fixed medical installations where whole

blood can be collected under a "closed system" and stored in refrigerated boxes for a period of five to seven days. It is expected that most of the blood collected for storage will be taken from proved group O donors, thus making it possible to inject this blood into recipients of all types.

Free Muscle Transplantation.—Prudente's method consists in the transplantation of a piece of muscle completely separated from its muscular body and transported through a skin tube. The sternocleidomastoid and pectoralis major are the muscles of choice for the face. This operation has been used in 4 cases. Three cases involved defects of the angle of the mouth and the cheek, 1 resulting from noma and 2 from cancer. The fourth was a case of cancer of the floor of the mouth involving the jaw and the inferior lip. Two cases of the first group have already been reconstructed both anatomically and functionally. The other 2 are in the last stages of restoration. The author stresses the following points: 1. Healing of the muscular skin flap is always by first intention, because the union is made between tissues of the same nature. 2. After the first stage, when the muscle strip is isolated before its transplantation, it is transformed into a fibrous tissue, but after that transplantation, when it lies close to the healthy muscles of the new region, it recovers its normal aspect, corresponding to a true rehabilitation of the tissue. 3. After a few months the grafted muscle recovers its function, probably as the result of nervous penetration from neighboring muscles, and the patient is able to perform every movement. Whistling and spitting are possible with real contraction of the grafted muscle. 4. Microscopic examination of the grafted muscle shows that its structure is perfectly normal.

Operative Results in Intervertebral Disks.—Grant reviews observations on 150 patients with ruptured intervertebral disks verified at operation. All of these patients had at least a six months follow-up period. Before operation 11 patients were bedridden, 27 were unable to do gainful work and 112 were working with disabilities. Of the 11 bedridden patients, 6 are back at their previous jobs, 3 are employed in less arduous labor and 2 are unable to work. Among the 27 unable to work preoperatively 17 are back at work, 6 are improved and 4 are unimproved. Of the 112 patients working with disability, 55 are cured, 47 are improved and 10 not improved following surgical intervention. The author also reviews the results of conservative treatment of 93 patients with an assured diagnosis of ruptured disk. Of 15 bedridden patients 9 have completely recovered and 3 have improved enough to carry on light work. Of 42 who were unable to work, 36 have recovered sufficiently to return to less arduous work; the other 6 are still not working. Thirty-six who were working with disabilities are still at work, although 24 of them have had to change their employment. On the basis of this assessment the author sees no reason to change the conservative attitude he has adopted in the past two years. Surgery is not, in his opinion,

the only treatment for this condition. Many of these patients will recover with rest, leg traction, back support and other nonoperative means. If this is unsuccessful, or if a recurrence of pain is noted, surgery should be considered.

Disability of Shoulder and Arm Due to Herniation of Nucleus Pulposus.—Michelsen and Mixer report observations on 8 cases of herniation of the nucleus pulposus in the lower cervical spine. There were lesions at the fifth cervical interspace in 4 cases, at the sixth in 3 and at the seventh in 1, with involvement of the sixth, seventh and eighth cervical roots, respectively. The clinical data were brought together in a syndrome that comprised root pain and local sensory and motor disturbances, as well as positive x-ray, cerebrospinal fluid and iodized oil findings. The distribution of the sensory abnormalities was compared with standard dermatome charts. In these cases the sixth cervical dermatome seemed to involve the scapula, the anterolateral aspect of the upper arm, the antecubital space, the radial forearm and its thumb and index finger. The seventh cervical dermatome seemed to involve the scapula, the posterolateral aspect of the upper arm and the dorsal surface of the forearm and the index and middle fingers. The eighth cervical dermatome seemed to involve the scapula, the inner and upper arm, the forearm and the little finger. The importance of a systematic neurologic examination in cases of pain or disability of shoulder and arm is emphasized in order to separate the apparently specific syndrome of cervical herniations of the nucleus pulposus from other extraspinal and intraspinal entities. All of the 8 reviewed cases were proved by operation. All the patients had various forms of treatment prior to their hospital admission, without permanent relief. Such measures comprised baking and massage, lamp treatments, strappings and head traction. One patient was injected locally with procaine hydrochloride. The laminectomy and removal of the disk fragment produced good results in 6 cases. In 1 case the improvement was not too impressive. In 1 case in which the disk fragment could not be removed for technical reasons the pain was relieved but the motor disability persisted.

Chronic Latent Hepatitis Following Catarrhal Jaundice.—Altschule and Gilligan state that there are now available in the literature records of the persistence of icterus as well as reports describing increased plasma bilirubin and decreased bilirubin excretory function in some patients who years previously had had an attack of catarrhal jaundice. Chronic gastrointes-

tinal complaints and chronic hepatic enlargement have also been reported as sequelae of acute catarrhal jaundice. The present report of laboratory and clinical studies made in an unselected series of 36 persons who had had catarrhal jaundice one to twenty-nine years previously similarly demonstrates in some cases the persistence for years of certain evidences of hepatic dysfunction. Hyperbilirubinemia was detected in 9 of the 36 patients. It is probable that the incidence of impairment of liver function was even higher, since the distribution of plasma bilirubin values revealed an abnormally large number in the high normal range. Nine subjects in the entire group had palpable livers and 1 a palpable spleen. The chronic latent liver disorder revealed by this study was not accompanied by symptoms and did not appear to be progressive. It is concluded that a mild, benign form of chronic hepatitis is frequent after catarrhal jaundice.

Methergine (Synthetic Ergonovine) in Third Stage of Labor.—Roberts reports observations on a new synthetic ergonovine which is known as methergine. This substance, which was synthesized by Stoll and Hofmann of Basel, Switzerland, is particularly important because of the potential shortage of rich ergot of rye. Methergine was first employed subcutaneously in 26 cases which were observed in the Department of Obstetrics of Stanford University Hospital. No systemic reactions were encountered in any of these cases. Methergine was then administered intravenously in the third stage, in doses of 1 cc. containing 0.2 mg., to 34 patients, of whom 6 were primiparas and 28 multiparas. The contraction of the fundus following methergine was stronger and of considerably greater intensity and duration than with the usual ergonovine preparations. No increase in the incidence of postpartum morbidity or subinvolution of the uterus was noted in this series. Experience with methergine has convinced the author that it is a useful, potent oxytocic of great value. Of particular interest has been the reduction of blood loss in the third stage of labor—not necessarily the lowering of the level within normal limits, but rather the elimination of those cases of severe hemorrhage of over 500 cc. In view of the small series, the results with methergine require further verification.

Penicillin in Treatment of Acute Empyema.—Butler and his associates dissolved penicillin in water to give a concentration of 1,000 units per cubic centimeter, and the dosage was adjusted to the size of the cavity. The sensitivity of the infecting organism having been established, the initial injection varied between 10,000 and 40,000 units, 20,000 being usual. As treatment proceeded, 10,000 or 5,000 units often sufficed. The authors treated 18 cases. Seventeen of these were infected. In 10 the invading organism was the streptococcus and in 7 the pneumococcus. In 1 patient with sterile traumatic hemothorax, treatment with penicillin prevented infection. The infected cases treated with penicillin show that, provided the infecting organism is susceptible, an empyema cavity can be sterilized by repeated aspiration of the pus and injection of penicillin and the toxic condition is thereby relieved. It is too early to assess the final results of the treatment, since further improvement is expected in some cases, while symptoms may yet develop in others arising from pulmonary fibrosis. The period required for final sterilization is unpredictable, since some cases showed recurrence after eight to ten days of continuous treatment, whereas some remained sterile after only five days' treatment. After sterilization there was the tendency for sterile pus to be formed in which minute gram positive cocci persisted. It seems possible that these organisms, although dead, may remain pyogenic. The source of these organisms and of normal cocci in cases of recurrence is probably to be found in the masses of fibrinous exudate lining the walls of the cavity, the removal of which might be expected to hasten sterilization and limit the formation of pus. To accomplish the removal of this exudate some recommend irrigation of the cavity with sterile saline solution before injecting penicillin, while others advise rib resection and removal of the fibrinous masses lining the cavity as soon as the infection is under control and the patient fit for the operation. There is little hope of avoiding a thickened pleura and rigid chest wall without removal of the fibrinous masses.

- Pituitary Cachexia Treated with Corticotrophic Hormone.**—Hemphill and Reiss describe the case of a woman whose menses ceased abruptly at the age of 39 without subjective menopausal disturbances. She became depressed, lost

appetite and imagined that her viscera were deranged and the bowels "stopped up"; she attempted suicide. She was thin, weak, and frail looking. The skin was extremely dry. The hair of the head was brittle and lusterless, that of the pubis and axillae scanty; muscle bulk was reduced. There was no assayable output of gonadotropic, corticotrophic or thyrotrophic hormones in the total urine of ninety-six hours; the output of 17-ketosteroids was only 2.6 mg. in twenty-four hours. Forty sudanophobic units of corticotrophic units were administered daily for twenty-four days. There was immediate improvement. Two months later a further course of daily injections of 25 units was given for fourteen days. This treatment resulted in complete restoration of weight and cosmetic features. This was not a case of anorexia nervosa. The psychotic depression was not relieved until a considerable time after physical improvement was complete. It is now two years since hormone treatment has been given, but the improvement has been maintained.

Propylene Glycol Vapor as Air Disinfectant.—Challinor and Duguid investigated the efficiency of propylene glycol vapor as an air disinfectant (a) in air continuously infected by atomization of suspensions of *Bacillus prodigiosus* and (b) in a crowded room with its natural, largely dust borne, air infection. The effect of single vaporizations of the glycol was found to be transient. Reduction of air infection could be maintained by continuous vaporization of the glycol or by single vaporizations repeated at short intervals of about ten minutes. Vaporization at the rate of 1 cc. of glycol per million cubic centimeters of air per hour produced a considerable reduction (about 85 per cent) in the naturally present air infection of a crowded room during the period of vaporization; perceptible mist formation, which might be found objectionable in practice, occurred at this dosage rate. Vaporization at lower rates did not result in mist formation but produced only small reductions in the air infection.

Treatment of Typhus with Anti-Typhus Horse Serum.—According to Wolman typhus in Addis Ababa is louse borne. Epidemiologic, immunologic and clinical studies have shown that it is epidemic typhus, identical with the European disease. The mortality varies from year to year and from month to month. The observations reported in this paper extended over a period of eighteen months and covered two major epidemics. The patients were mostly Ethiopians. All patients admitted with symptoms of typhus were given a special chart with a serial number. Venous blood, taken on the day the provisional diagnosis was made, was sent to the Medical Services Laboratory for Weil-Felix and Weigl tests. Patients with even numbers were given symptomatic treatment only. Patients with uneven numbers were given the same symptomatic treatment, plus serum. The total number of patients was 440. For the

preparation of the serum the Ethiopian army lent 2 horses. Living rickettsias contained in the intestines of lice, prepared for Weigl vaccine, were injected into the horses, usually every five to six days, in doses increasing over a period of two and one-half months. The horses were then bled twice (five and ten days after the last injection). In each subsequent month a further series of injections was given (ordinarily 250, 375 and 500 louse intestines) followed by two further bleedings. The blood was collected in large sterile bottles one-tenth full of 5 per cent sodium citrate, and after two or three days the supernatant serum was siphoned off and enclosed in rubber capped bottles, with merthiolate or phenol as a preservative. The dosage of serum was 20 cc. subcutaneously twice on the first day and once on three succeeding days. The mortality of the treated group was 3.6 per cent, compared with 10.9 per cent in the controls. The serum seemed to shorten the illness and reduce the incidence of psychotic symptoms. Its influence was greater when given early in the illness.

March Hemoglobinuria.—This is a condition in which physical exertion, usually in the form of marching, is followed by the passage of red or dark colored urine. The author lists the following salient features of march hemoglobinuria: 1. It occurs in young males, usually in the second or third decade. 2. It is related to exercise in the upright position. 3. Constitutional symptoms are absent or mild. 4. The course is benign. The condition appears to have no permanent ill effects, and it progresses without specific treatment toward ultimate spontaneous recovery, which usually takes place within a period of months or a year or two after the initial attack. Occasionally it is of longer duration. In 1 case periodic attacks occurred for seven years, and in another case attacks occurred intermittently for twenty years. The essential nature of the condition—that is, its relation to exercise in the upright position and the absence of associated physical abnormalities or after-effects, may tend to cause delay in diagnosis. This occurred in the case reported. A corporal who enlisted in the Australian Military Forces at the age of 18 noticed that his urine was "dark" after more than usually strenuous military training exercises, but as he felt otherwise quite well, and as the condition did not persist, he did not report this attack at the time. Several months later another attack occurred, associated this time with some pain in the groins. Eight hours later he reported at the hospital. No abnormalities were detected on physical examination. Three days after his return to camp another attack occurred in which the passage of "dark" urine was associated with pain in the right loin. He was admitted to the hospital, but again no abnormalities could be detected. At several successive hospitalizations numerous tests were made, and finally it was discovered that a march of forty-five minutes' duration was followed by hemoglobinuria. The author points out that the usual program of investigations designed to demonstrate or exclude the more common causes of hematuria or the presence of abnormal pigments in the urine is almost certain to be carried out with the patient at rest. By virtue of this fact a sojourn in a hospital for investigation will actually tend to prevent the occurrence of march hemoglobinuria and so fail to reveal the symptoms of which the patient complains. Unless, therefore, the possibility of march hemoglobinuria, which at least in its severe forms is rare, is kept in mind, considerable difficulty and delay may occur in confirming the patient's statements and establishing the diagnosis.

Trichinosis in Children. F. Martinez L. de G.—p. 297.
Pulmonary Atelectasis in Children and Its Relation to Primary Tuberculosis.—p. 316.

Neurologic Complications of Typhoid.—Bambach and Guerrero present the histories of 2 children with typhoid who had neuropsychic complications that masked the course of the typhoid. The first child, aged 5, had hemiparesis of the right side, which was probably of central origin. The process was most severe in the lower extremity, and since there was no involvement of the tongue it is assumed that the lesion was located in the upper part of the left Rolandic convolution. The neurologic symptoms completely disappeared; a neurologic examination made fifty-eight days after hospitalization was negative. The diagnosis of typhoid was amply corroborated by a positive Widal reaction and a typical blood picture. The second case concerned a child aged 6 who was hospitalized with an undetermined infectious disease. The symptomatology indicated involvement of the nervous system, but the case remained undiagnosed for a long time. Finally blood culture yielded Eberth's bacillus, and a 1:100 positive Widal reaction was obtained. The authors reviewed 100 cases of typhoid that were observed at their hospital during recent years. Excepting cases with only dulling of the sensorium, there were 15 with neurologic signs. This contrasts with only 1.73 per cent of neurologic involvement in an epidemic in Lyon in 1928-1929 and with only 4 per cent reported from Uruguay. The authors think that this diversity of percentages speaks for differences in the type of epidemic or for regional peculiarities. In the cases reviewed by them the mortality of the cases with neurologic involvement was 23 per cent. The cases which do not have a fatal outcome are usually reversible and have no sequelae.

Münchener medizinische Wochenschrift, Munich

Problem of Combined Treatment with Strophanthin and Glucose. H. Lachmann.—p. 935.

Differential Diagnosis of Catarrhal Jaundice and of Epidemic Hepatitis.—Mancke and Siede report their observations in 456 cases of so-called icterus catarrhalis. Three groups are differentiated: 1. The specific icterus catarrhalis, which starts with intestinal symptoms, frequently without any rise of temperature. Alimentary or endogenous intestinal toxins may reach the liver cells by the portal vein or by the intestinal lymph radicles. It is characterized by its deleterious effect on the membrane. Toxic edema of the liver, serous hepatitis combined with destruction of liver cells, may be the result ("forme fruste" of the acute and subacute atrophy of the liver). 2. Capillary cholangitis, which may develop by ascending from the large bile ducts or which may be of hematogenous origin; in the latter case one may have to deal with a cholangitis of excretory type. The injurious agent is bacterial in the majority of these cases. A lesion in the area of the "intermediary portion" of the bile ducts may occur first. The bile ducts are lined with epithelium and are connected with the intercellular bile capillaries of the liver; "intermediary portion" is the term used for this first portion of the bile ducts. It deserves special morphologic consideration as a particularly vulnerable area of the bile ducts. An icterus of fine mechanical origin from obstruction in the area which contains the sources of bile may result from the lesions in the aforementioned area. 3. The specific hepatitis. Direct destruction of liver cells may be caused by a hematogenous toxin of liver cells whose chemical structure may be more or less ascertained. Arsphenamine, cinchophen, chloroform and phosphorus may be mentioned. Fatal hepatargy may result from toxic hepatitis induced by mushroom poisoning.

Book Notices

The Chemistry and Technology of Food and Food Products. Prepared by a Group of Specialists Under the Editorship of Morris B. Jacobs, Ph.D., Senior Chemist, Department of Health, City of New York. Volume I. Cloth. Price, \$10.50; \$19 per set of 2 volumes. Pp. 952, with 79 illustrations. New York: Interscience Publishers, Inc., 1944.

This is the first of two volumes devoted primarily to a complete description of the technical aspects of foods, their sources, composition, processing and also the related body physiology. Each chapter has been prepared by a specialist in the field; altogether forty-one individuals collaborated in the work, with the whole edited by one well versed in the broad subject of food control. Two of the six sections of this treatise on foods comprise volume I. The first deals with fundamental food chemistry and body processes related to foods. The chemical discussion of the basic food constituents is extensive and well done. The physiologic coverage is less complete, but this subject may be considered of secondary interest in this book. Use of the term "vitagen," referring to the so-called essential fractions of the basic food constituents, is of dubious value. The brief mention of disease conditions resulting from lack of food substances is incomplete. For example, iodized salt is not included as a food source of iodine, the preventive of simple goiter.

The second section of this volume presents widely diversified information on every basic type of processed and unprocessed foodstuff, as well as beverages and condiments. For each class a historical sketch is given followed by information on growth and production, varieties available, chemical composition, methods of preservation, government controls and standards of identity, as well as other facts of interest. The numerous tables offer valuable sources of reference data, although some of the data so supplied are not the most recently available and in some instances the vitamin values are given in units now considered obsolete. The presentation is strictly scientific throughout, with support of frequent references to the literature and inclusion of a bibliography at the end of each chapter. This volume is a combination of textbook on food chemistry and encyclopedia of basic food information. It represents an ambitious undertaking which has gathered together a great deal of information, heretofore unrelated, for the benefit of science and industry.

Lippincott's Quick Reference Book for Medicine and Surgery: A Clinical, Diagnostic and Therapeutic Digest of General Medicine, Surgery, and the Specialties, Compiled Systematically from Modern Literature. By George E. Rehberger, A.R., M.D. Twelfth edition. Fabrikoid. Price, \$15. Pp. 1,460, with 305 illustrations. Philadelphia, London & Montreal: J. B. Lippincott Company, 1944.

In this edition the sections on gynecology and genitourinary diseases have been entirely rewritten, and the list of drugs has been revised in accordance with the new Pharmacopoeia and National Formulary. The publisher points out that the advances in medicine have been so great that scarcely a page of the book has gone unchanged. Special attention is called, however, to new material on chemotherapy, shock treatment, burns, deficiency diseases and nutrition. Many new color plates have been added to the present edition of this well known encyclopedia.

Health Counseling for Girls. By Margaret L. Leonard, Ed.D. With a foreword by Ruth Strang, Ph.D. Cloth. Price, \$1.50. Pp. 131. New York: A. S. Barnes & Company, 1944.

This is a valuable book for any one who has to interview girls in connection with physical education, health education or administrative work (advisers and deans) and for personnel directors in industries employing many women. The book is devoted to an exposition of techniques. It starts with a chapter in which are summarized interviews with eight girls presenting different health and personal problems. These interviews are analyzed in terms of approach, interview techniques, the use of records and suggested ways of asking questions. The author concludes that, allowing for emotional disturbance, shyness, suspicion and the like, adolescents, for the most part, appear to try sincerely to give honest answers to questions. The second chapter deals with health counseling as part of a total school program. This includes much valuable information as to the

role of the counselor and how it can best be discharged. Chapter III deals with specific health counseling problems, such as loss of weight, absence due to abdominal pain and nausea, return to regular physical education after illness, dental care problems, deafness, health in relation to selecting a college and the lighter school program after a month's absence due to pneumonia, nail biting, cardiac patients and stair climbing, skin disorders and so on. Extreme overweight or underweight, menstrual problems, fatigue, posture, faulty elimination, personal fastidiousness, difficulties with school work, boy and girl relationships and getting along with other girls are other topics dealt with. Chapter IV deals with the interrelationship of counseling and group activities among adolescents. In these four brief chapters the topics are dealt with effectively, clearly and briefly but not dogmatically. This should be an excellent reference and handbook for the purposes suggested in its title.

The Blood Plasma Program. By James A. Phalen, M.D., Colonel, U. S. Army. Issued by the Office of Medical Information (Under Grant of the Johnson & Johnson Research Foundation). National Research Council, Division of Medical Sciences. Paper. Pp. 67. Washington, D. C., 1944.

Spontaneous Pneumothorax. By James J. Waring, M.D. Issued by the Office of Medical Information (Under Grant of the Johnson & Johnson Research Foundation). National Research Council, Division of Medical Sciences. Paper. Pp. 34, with 2 illustrations. Washington, D. C., 1944.

Antimalarial Drugs: General Outline. By Orsel Temkin, M.D., and Elizabeth M. Ramsey, M.D. Issued by the Office of Medical Information (Under Grants of the Carnegie Corporation and the Johnson & Johnson Research Foundation). National Research Council, Division of Medical Sciences. Paper. Pp. 128, with illustrations. Washington, D. C., 1944.

These three mimeographed pamphlets, all issued by the Office of Medical Information of the National Research Council, are brief informative monographs on timely subjects. Of the three under review, the one on "Antimalarial Drugs" is the most extensive, since it includes a bibliography of 237 titles. The publication of these brochures has been made possible by grants from the Johnson and Johnson Research Foundation, and in the case of the publication on "Antimalarial Drugs," with the help of the Carnegie Corporation as well. All three publications are useful and authoritative within the limits of the space employed.

Sex Education in Schools and Youth Organizations. Board of Education Educational Pamphlet No. 119. Paper. Price, 15 cents; 6d. Pp. 22. New York: British Information Services; London: His Majesty's Stationery Office, 1943.

In Britain, as in the United States, sex education is approached gingerly, with many misgivings, false starts, a furtive rather than forthright approach. Every one agrees that it should be done and every one gives a sigh of relief when some one else shows signs of doing it. Lectures, conferences, pamphlets and books have all been tried in Britain, as they have in the United States, and it all comes down to the fundamental question of who is doing the teaching. Given a teacher of appropriate personal qualifications, all goes well; lacking such a teacher, no system and no literature has any effectiveness or validity. In Britain, as in the United States, "it is the general view that sex instruction should be given as a related part of a wider course, especially biology, so that sex and reproduction may be introduced in their proper places without undue emphasis. Many schools, however, are without biology teaching and in others the biology staff are not anxious to give the instruction. In these cases special classes are often necessary." This could have been written with equal validity about the American situation, as could this: "Invariably parents are relieved to know that the question has been discussed but get foolishly hot and bothered if their wishes are consulted beforehand."

The Medical Annual: A Year Book of Treatment and Practitioner's Index. Sir Henry Tidy, K.B.E., M.A., M.D., and A. Rendle Short, M.D., B.Sc., Editors. Sixty-Second Year 1944. Cloth. Price, \$7. Pp. 404, with illustrations. Baltimore: Williams & Wilkins Company, 1944.

This yearbook continues through the war years and constitutes essentially a collection of abstracts largely from British and American publications. There are occasional rare references to the literature of central Europe, and these are mostly in relation to subjects concerned in the war.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

ADOPTION FROM FAMILIES OF POOR STOCK

To the Editor:—About two months ago I delivered a set of twins in the home. They weighed 6 and 6½ pounds (2,725 and 2,955 Gm.), and were the eighth and ninth babies of this mother. At about 1 month of age they were dehydrated and weighed about 4 pounds (1,815 Gm.) each, and since they were not well cared for by the mother they were entered in the hospital. The babies are back to normal now, and the mother wants some one to adopt them. One of my best friends has asked my advice about adopting them; how to answer him is my problem. The father of the children is in the penitentiary for stealing; the oldest son is in the county jail for the same offense. The mother is ignorant. The other children look and act well. The family is at the lowest economic level. What are the chances for these babies to inherit the traits of their father and brother?

M.D., Alabama.

ANSWER.—While the general opinion is that children do not inherit acquired characteristics, in selecting a child for adoption the average foster parent should feel that the stock of the baby is at least average in order that he may get an even break in setting the environment for the child he takes into his household. It would be decidedly questionable to adopt children with the type of family history given in this case. It is quite evident that they come from less than average stock. The only thing which would change this opinion would be some additional information about the ancestry of this family which might be more favorable.

FEVER OF UNKNOWN ORIGIN

To the Editor:—A man aged 39 was admitted to the hospital because of nine days of remittent high fever of 105 to 99 F. daily, which did not respond to sulfonamides. The patient had had an occasional nonproductive cough and at the start of his illness had had a transient charleyhorse in his right leg, which had not annoyed him since. There were no other symptoms. The patient had not traveled outside of New York City, and there was no known contact with illness. The past history was entirely normal. On admission the patient appeared acutely ill and was shivering. Physical examination was entirely normal. The urine was normal. The blood count showed 11,000 white cells with 74 per cent polymorphonuclear cells, 4 per cent monocytes and 22 per cent lymphocytes. Of twelve blood cultures, nine were sterile and three showed *Streptococcus viridans*. On one occasion blood agglutinations showed typhoid positive 1:80, paratyphoid A and B each positive 1:160. A smear for malaria was negative. The temperature curve by days was 105, 98.6, 102, 98.6, 100 F. and normal thereafter. Spinal fluid examination was normal, as was an electrocardiogram and a chest plate. The stools showed no ova or parasites. What significance is attributable to the repeatedly positive culture for *Streptococcus viridans* in the absence of any other evidence for bacterial endocarditis? What type of treatment and follow-up are indicated? Can you suggest a diagnosis?

M.D., New York.

ANSWER.—Cases like the one described in which diagnosis cannot be made are not uncommon. It must be expected that not every case can be diagnosed. There are, no doubt, still some infections whose cause is unknown, and in other instances well known infections may occur without telltale evidence by which diagnosis may be made.

Data given in the case in question are incomplete. At what season of the year did it occur? What was the sedimentation rate of the erythrocytes? What was the nature of the "charleyhorse"? Charleyhorse in Gould's Medical Dictionary is described as "a rupture or strain of muscle or tendon fibers generally resulting from athletic efforts." If the patient had this condition, the local injury and hemorrhage into the tissue, myositis, phlebitis or cellulitis may have served as the source of the trouble, which could begin with a chill, last nine days with remittent fever and not be influenced by sulfonamide therapy. On the other hand, the charleyhorse may have been mistaken for a small embolus, phlebitis or other condition.

The significance of *Streptococcus viridans* in the blood on several occasions is uncertain. This ubiquitous coccus may appear transiently and apparently harmlessly in the blood stream in many febrile diseases, and its presence has caused confusion in mistaking it for the cause rather than as a commensal. On the other hand, the attack described may be the first evidence of subacute bacterial endocarditis. If the patient remains well, no treatment is necessary. The patient should nevertheless be examined at intervals of several weeks for any abnormalities, especially for fever and evidence of cardiac valvular injury.

To suggest further diagnoses would be guesswork, but hidden, symptomless abscess (renal, perirenal, prostatic) may be mentioned.

PANCREATIC EXTRACTS FOR PERIPHERAL VASCULAR DISEASE AND ARTERIOSCLEROSIS

To the Editor:—Of what use are pancreatic extracts in the treatment of peripheral vascular disease and arteriosclerosis? I am familiar with Dragstedt's experimental use of lipocaine in arteriosclerosis and have read the discussion of Wolff's "Desympatone" *The Journal*, Oct. 26, 1940, (p. 1454), which is not very conclusive. Have there been any good clinical studies of the effect of a fat mobilizing pancreatic extract in these conditions? Is a reliable preparation of this sort available for clinical use?

Elaine M. Thomas, M.D., Chicago.

ANSWER.—There have been several clinical studies of the use of pancreatic tissue extract (insulin, histamine and choline free) in peripheral vascular disease. Whatever beneficial effects have been obtained with these extracts have been attributed by the users not to a fat mobilizing enzyme but to a vasodilating substance titrated according to its ability to neutralize the effects of epinephrine. It is understood that this vasodilating substance is not peculiar to pancreas but is found in several other tissue extracts.

Klein, Saland and Zurrow (Pancreatic Tissue Extract [Insulin Free] in the Treatment of Peripheral Vascular Disease, *Ann. Int. Med.* 18:214 [Feb.] 1943) found that tissue extract injected intramuscularly in 3 cc. doses twice a week for relatively long periods (six to eighteen months) produced improvement in claudication time and rest pain but had no effect on existing tissue changes. They could not confirm the observations of Fisher, Duryea and Wright (Deproteinized Pancreatic Extract [Depropanex] *Ann. Heart J.* 18:425 [Oct.] 1939) that pancreatic tissue extract produced an immediate improvement in claudication time. Gorham and Climenko (The Role of Insulin Free, Histamine Free Pancreatic Tissue Extract in the Treatment of Peripheral Vascular Disease, *Ann. Heart J.* 25:486 [April] 1943), using the same type of pancreatic tissue extract, found it to have a beneficial symptomatic effect on nearly all patients with peripheral vascular disease when vasospasm was a prominent feature. In their series, patients obtained relief for periods of one to six months with administration at intervals of two to seven days. The pancreatic tissue extracts used in these studies included Depropanex (Sharp and Dohme), Tissue Extract No. 568 (Sharp and Dohme) and Pancreatic Hormone (Grant).

There have been no extensive clinical studies made of the effect of fat mobilizing pancreatic substances on arteriosclerosis and peripheral vascular diseases. Choline and lipocaine have thus far been studied chiefly in their effects on experimental animals. The standardization of lipocaine is difficult. Its use in a single case of xanthoma tuberosum (Rosenak, B. D.: *Ann. Int. Med.* 19: 514 [Sept.] 1943) was reported to have been without effect on the lesions or plasma lipids. However, in following the implications of this question we presume to possess a greater knowledge of the pathogenesis and course of arteriosclerosis than is the case at present. It is not at all certain that arteriosclerosis is dependent primarily on a hyperlipemia, although Leary (*Arch. Path.* 32:507 [Oct.] 1941) has offered an interesting series of demonstrations to show that cholesterol esters are deposited in the subendothelium of the aorta by wandering tissue cells and the arteriosclerotic process thus initiated. Others believe that the accumulation of lipids in an artery is secondary to medial injury. Furthermore, Leary differentiates between atheroma formation in the subendothelium, which he states is a reversible process, and atherosclerosis, which is a permanent chronic process due to prolonged stay of cholesterol esters in the intima. He believes the latter responsible for most of the important lesions listed under arteriosclerosis. The ability to remove atheromas, according to Leary, is chiefly a cellular function, being performed by fixed cells, "lipolytic fibroblasts," and this ability disappears gradually with age and other factors. However, even if it is assumed that these demonstrations open an avenue of therapy, it is difficult to see how proper clinical evaluation of any chemical agent can be made on the basis of its ability to mobilize fat from the blood vessels, since atherosclerotic changes cannot be detected by x-ray examination and most workers agree that there is no fixed relationship between blood lipid levels and arteriosclerosis.

ACETARSONE FOR SYPHILIS

To the Editor:—What is the consensus concerning the use of acetarsone (stovarsol) in the treatment of prenatal syphilis? I am particularly interested in the results of experiments in the use of acetarsone and the treatment of syphilis in adults whose veins are so small as to make intravenous treatment impossible. Cecil A. Z. Sharp, M.D., Joliet, Ill.

ANSWER.—Acetarsone is not suitable for the treatment of syphilis in adults, whether orally or by any parenteral route. The drug produces a high incidence of serious toxic reactions and cannot be recommended.

SHOCKLIKE STATE AFTER PNEUMONIA

To the Editor:—A man with an extensive right lower lobe pneumonia, probably pneumococcal, did not respond to sulfadiazine therapy in forty-eight hours and was given penicillin. On the fifth day of his illness his temperature began to drop and within twenty-four hours it dropped to 97 F. With this drop in temperature his pulse became rapid and thready, his color was ashen gray and his respirations were rapid and shallow. The blood pressure was 100 systolic and 88 diastolic. There was no pulmonary edema. There was no evidence of congestive heart failure. The heart sounds were of fair quality. I would appreciate the following information: 1. What is the probable mechanism of this reaction? 2. Are hemoconcentration, diminished circulating blood volume, capillary stasis and arteriolar spasm present? 3. What form of therapy is indicated to combat this emergency? 4. Are epinephrine, nikethamide and caffeine with sodium benzoate of value or are they contraindicated? 5. Are plasma, blood transfusion and parenteral fluids of value?

Captain, M. C., A. U. S.

ANSWER.—The type of alarming reaction described, for some unknown reason, seems to occur more commonly after the bacterial pneumonias which complicate influenza, as in the pandemic of 1918-1919, than after typical pneumococcal pneumonia. It also occurs after viral pneumonia, influenza, typhus and other acute infections. Its occasional occurrence during the crisis of pneumococcal pneumonia gave rise many years ago to the undue apprehension which still attends that phenomenon. It may occur at any time during the course of the disease.

The replies to the questions are as follows:

1. The mechanism of the reaction is poorly understood, but the condition is evidently related to shock or the shocklike state. Whether it is the result of a general "let down," asthenia or exhaustion after a severe disease or the exhaustion, failure or disturbance of a specific center or system such as the respiratory center (Colc. R. I., in Nelson's Loose Leaf Living Medicine 1:203, 1920-1928. Reimann, H. A.: The Pneumonias, Philadelphia, W. B. Saunders Company, 1938, p. 59) or of vasomotor paralysis and failure of the circulatory system (Cecil, R. L.: Arch. Int. Med. 41:295 [March] 1928. Perry, C. B.: Quart. J. Med. 3:273 [April] 1934. Reimann: The Pneumonias, p. 68) is unknown. When it coincides with the crisis it may result from an inability of the particular system involved to readjust itself quickly to the suddenly changed condition arising between illness and recovery. Some (Warfield, L. M.: THE JOURNAL, March 14, 1936, p. 892) have ascribed the cause to "toxins" of the causative agents or to toxins resulting from their interaction with the tissues of the host. There is much to suggest a disturbance of the nervous system as an important factor. In the case described, signs of failure of the respiratory center seem to predominate over those of circulatory failure. See also Heffron, R.: Pneumonia, New York, Commonwealth Fund, 1939, page 545, for further discussion and references.

2. Hemoconcentration, diminished circulatory blood volume, capillary stasis and arteriolar spasm probably are present as in the other shocklike states, but the writer is unaware of any particular studies being made of the condition occurring specifically during the crisis of infectious disease.

3. The usual measures prescribed for the treatment of shock are indicated (see Warfield, *loc. cit.*).

4. The commonly used drugs mentioned have little or no value.

5. Parenteral injection of fluid, particularly of plasma, is usually advocated, but the problem of getting the fluid to move in the circulatory system seems to be of more importance than of simple replacement.

INTRAVENOUS ADMINISTRATION OF SALICYLATES
—ACTION OF COLCHICINE

To the Editor:—Because of the local widespread use of intravenous sodium salicylate and the inconvenience caused both patient and doctor thereby, could you please tell me if the intravenous use has any advantage over the oral use in patients who tolerate the drug well by mouth? As a second question I should like to ask of what particular value in cases of arthritis, neuralgia, or myalgia, where gout is no factor, would the intravenous preparation of sodium salicylate 1 Gm. and sodium iodide 1 Gm. with colchicine 0.65 mg. have over the administration of these substances by mouth? As a third question, Has colchicine any rationale in the treatment of any other disease than true gout?

E. W. Seward, M.D., Hanford, Wash.

ANSWER.—Oral administration of the ordinary doses of sodium salicylate relieves the symptoms of rheumatic fever promptly and completely, unless vomiting sets in before a sufficient amount has been absorbed. If the drug is tolerated there would be no advantage in intravenous administration, and there would be the disadvantage of inconvenience and also some danger of colloidoclastic shock if the injection is made with ordinary speed, as shown by Hanzlik, Dé Eds and Trinter (Arch. Int. Med. 36:447 [Oct.] 1925).

However, a new slant has been given to intravenous salicylate medication by A. F. Coburn (Bull. Johns Hopkins Hosp. 7:

[Dec.] 1943). He conceives the salicylate action as an interference with the inflammatory process which produces the cardiovascular injury, especially in the polycyclic recurrences of children and young adults. This antiphlogistic salicylate effect is reflected in the return of the blood sedimentation rate. It is perhaps explainable by the prevention of the precipitation of antigen by antibody, which has been demonstrated in the test tube. It is proportional to the salicylate level of the plasma. Coburn reports that plasma concentrations of 10 to 20 mg. per hundred cubic centimeters, which are obtained by the customary dosage and which relieve the symptoms satisfactorily, do not control the inflammatory process sufficiently to obviate the cardiovascular injury and that this requires plasma levels of at least 35 mg. per hundred cubic centimeters, which can be attained by daily administration of 10 Gm. of sodium salicylate. This may be done by oral administration, but it can be accomplished much more promptly by intravenous drip and, according to Coburn, with less nausea and other salicylism. He advises 10 Gm. of sodium salicylate in 1,000 cc. of 0.9 per cent sodium chloride solution by intravenous drip during four to six hours daily for six days (in severe cases, 20 Gm. in 1,000 cc. in eight hours); then 10 Gm. by mouth daily in divided doses for two weeks or more until a normal sedimentation rate has persisted for a week. This is very different from casual intravenous injections. It is a subject for controlled study, not for perfunctory routine use. Coburn's results are promising, but he concedes that the series is too small to discount the variable course of rheumatic fever.

Intravenous administration always involves some elements of risk and should be chosen only if the indications are clearcut; the advantages definite and the dangers minimal. Mixtures rarely fulfil these requirements; there is no therapeutic advantage in the intravenous injection of a salicylate-iodide-colchicine mixture, and it would be difficult to defend such practice in case of untoward reactions.

The action of colchicine in gout is unique and has not been adequately explained. It is effective only with doses that verge on the toxic. It has not been shown to be effective in other conditions, and such use is inadvisable especially in view of its toxicity.

FUNGUS INFECTION OF NOSE

To the Editor:—A white man aged 30 has had a chronic vasomotor rhinitis for the past five years. Skin tests for possible allergy revealed a 3 plus reaction to dust and a 1 plus reaction to chocolate, rice, pear, cherry, cinnamon, grasses and ragweed. Allergic management failed to give relief. Following chemical cauterization seven months ago of the right inferior turbinate there was a severe aggravation of the symptoms. X-ray examinations of the sinuses were negative on three occasions, but clinically, during the winter, the patient has had sinusitis. Nasal smears on three occasions were negative for eosinophils but did reveal rather numerous yeast cells (2 to 3 per field). Cultures to identify the yeast organisms were unsuccessful on three occasions because of contamination with air borne molds. Owing to the character of the mucous secretion (thick, white, sticky) one is led to believe that this finding of yeast cells is of some significance. Will you kindly discuss the problem of nasal fungus infection and its management?

M.D., Illinois.

ANSWER.—Castellani says that "yeastlike and other fungi are often observed in the nasal mucus; they may play only a saprophytic role or they may give rise to an inflammation of the mucosa."

True yeast infection of the nasal mucosa and sinuses must be rare in this country at least. Its occurrence is not mentioned in a single one of a dozen well known textbooks on rhinology.

All observers are agreed that the commonest pathogenic fungi to be seen in the nose belong to the Aspergillus family. Practically all observers are agreed also that the symptoms of fungous infection of the nose closely resemble those seen in allergic rhinitis. Especially are the bouts of sneezing emphasized.

The yeast cells described in the query, because they appeared after chemical cauterization of the nasal mucosa, may not be playing a pathogenic role but might be saprophytic in nature. Granting for sake of argument that they are truly disease causing, the treatment, which is far from being well defined, will vary, depending on whether the nasal mucosa alone or the accessory nasal sinuses (particularly the maxillary) are involved.

If the nasal mucosa alone is involved, iodine appears to be a favorite remedy. Lugol's solution may be given by mouth in increasing doses; so also may potassium or sodium iodide be given in the conventional amounts. There seems to be little said or done about the use of antiseptics or other medicaments locally in the nose.

When the disease is present in the sinuses (most often the maxillary) the usual irrigations should be given, according to most authorities, good reason for removing the diseased mucosa operatively, preferably by way of a Caldwell-
